PREFACE TO THE SECOND EDITION

There are certain activities in our lives that seem to be endlessly repeating themselves: we witness an apparently endless construction of houses, office buildings, roads and highways, and other infrastructures; there is the preparation and consumption of foodstuffs; there is the daily maintenance of the quarters we live in; there are the recurrent activities governing our use of the markets, small and big; and so on and so forth.

Similarly, writing articles and essays may, for some people, seem to have the same repetitive and perhaps even monotonous character. Still, there is a difference. Writing (or for that matter, all communicative action) is always directed at a person or group of persons; even the most monologic self-expressing poetry always addresses somebody (even though, in extreme cases, the audience is restricted to the poet him-or herself). In addition, the repetitive character of, say, housework may prompt our easy-going consorts to protest against the making of beds or the cleaning of kitchens, with the motivation that ‘beds have to be made again anyway, so why not just let them be’, or: ‘dust is going to happen, so why not just adjust ourselves to a lower than needy standard of cleanliness’. In contrast, activities having to do with communication (in particular, writing) do not only affect the author (the ‘originator’, or *auctor*, with an old-fashioned term), but also, and perhaps to an even higher degree, the ‘end user’: the recipient, in our case, the reader.

But, some reader might object, what has all this to do with the current (concise) encyclopedia of language and linguistics that I am looking at right now? The answer is that encyclopedias, like all works of letters, presuppose our cooperation as readers. In and through the act of reading, we align ourselves with the author whose text we are perusing and with whom we are cooperating. And even though encyclopedias may seem to embody just what the word means: an all-round *paideia* (which is the Greek word for ‘upbringing’), to a cursory observer it may seem that such works only pretend to satisfy an individual’s desire to know a factoid or two, or to delve a little deeper into a certain area of knowledge. What is often overlooked is the interactive feature that is built into the very essence of encyclopedic work, no matter how apparently passive in character on the part of the reader.

It is no secret that many encyclopedias have been the forerunners of revolutions, as I pointed out in the Preface to the first edition of this Concise Encyclopedia. And what I wrote back in 1998 is just as true today as it was then:

The purpose of an Encyclopedia, according to the original (1750–1769) *encyclopédistes*, the French literates and philosophers Denis Diderot and Jean le Rond d’Alembert, is to enlighten the population in order to make them choose the right way of leading their lives, free from the encumbrances of false beliefs and authoritarian doctrines. This apparent innocent and worthy aim had much wider and more profound consequences for society than its proposers could ever have foreseen, as we now know, with the benefit of historical hindsight. Two hundred years after the American, the French, and countless other revolutions, the encyclopedia has become a standard household fixture, and it is hard to imagine, by looking at the impressive, often leather-bound volumes that adorn the bookshelves of better-off households around the planet, how the original ideals of democratizing enlightenment could have had such strong political, even revolutionary side effects. (Mey 1998:xxv)

By the double token of being iterative and revolutionary, encyclopedias, while pretending to codify the knowledge they conserve and propagate, also reflect the societal interaction that is at their base. And this is, finally, why encyclopedias have to be constantly updated and ‘re-cycled’.

The British author Patrick Leigh Fermor describes, in one of his erudite ‘travelogues’, how he, as a young man roaming across the old Hapsburg domain, always found solace in the encyclopedias he discovered in the libraries of the manors and castles to which influential friends had given him introductions. Thus, the traveler found himself “poring over *Meyers Konversationslexikon*” during his stay at a castle in Rumania, while trying to update his knowledge of Central European history (Hungarian and Transylvanian in particular; Leigh Fermor 2005: 101)—in more or less the same way that I, in an earlier period of my life and some twenty years later, helped by *Meyer*, familiarized myself with the beautiful railway stations and city halls that had once adorned cities like Metz and Strasbourg in what had been the (then) German *Reichsland* Elsass-Lothringen. I recall the historic *frisson* I experienced, due in part to the fact that many of those magnificent building had long since fallen prey to the combined forces of war and regressive architectural ideologies, posing as progressive notions.

The ‘melancholy of art’, *melanconia dell’arte*, that I perceived contrasted with the urgent need to move on with history, in the same way as it happened for the English author years ago, during a journey through a landscape that was in continuous flux, always on the brink of disappearing into the local and historical horizon, only experienced by ‘being there’, in real life or in the vicarious existence of an encyclopedia, and by moving ahead in an irreversible, and in a way perverse, penetration.

As far as pragmatics is concerned, such a journey provides us with an apt metaphor, both with regard to the landscape traveled and to the various intellectual landmarks and influences encountered there. It seems safe to say that the pragmatic landscape is not only in flux, but that its movements and tendencies have steadily accelerated their courses. Thus, from a humble beginning at the remote outposts of philosophy and linguistic semantics, pragmatics has developed into a vast realm where often conflicting theories and practices reign—just as it was the case for our Brit, traveling the always unruly and undefinable territories that at one time were loosely integrated components of the Austrian-Hungarian *kaiserliche und königliche* twin monarchy, the “*k.u.k. Doppelmonarchie*”, from the years before the Great War. But also, just as it is not only interesting, but useful for us to learn about happenings in those parts in the twilight between the two world wars, and confront them with the situation as it has evolved and especially as it is present to our minds today, so too is it useful, nay necessary, for us to reflect on the developments of our discipline ever since the days of John L. Austin and his burgeoning speech act theory. And in this respect, the new (second, 2006) edition of the mother volume to the present work, the *Encyclopedia of Language and Linguistics* along with its present, concise offshoot, seem to be timely undertakings.

If one were to ask what in particular has changed since those early times, the answer may be that pragmatics has become a ‘discipline’ in its own right, rather than a somewhat ill-defined by-product of other branches of language studies. The notorious ‘wastebasket of semantics’ comes to mind: an expression due to Yehoshua Bar-Hillel, who considered pragmatics more or less as uncharted territory, a bit like those Western expanses in America where a man still could do whatever he wanted to do and get away with it, as no rules or regulations had yet been invented to provide law-based security and establish rule-driven well-formedness. In contrast, we observe a trend towards what could be called a ‘legalization’ of pragmatics, starting in its earlier development and continuing until the present day. Even though it still is too early to speak of a unified scientific discipline (a term which may more properly be applied to other branches of linguistics, such as phonetics or syntax), there is no doubt that pragmatics, as a discipline, has come into its own.

It would be wrong, however, to consider the growth and deployment of pragmatics as a science uniquely as a ‘breaking away’ from older disciplines like semantics or syntax. Rather, the development that led to the rise of pragmatics started as a linguistics-internal movement (inspired by the philosophy of language of the Austinian type), whose ultimate endpoint could not be foreseen (and, as many will say, is still out of sight and reach). Whereas, on the one hand, certain developments in pragmatics may have been triggered by the descriptive aporias and insufficiencies involved in purely semantic or even syntactic ways of considering language, on the other it is equally true that many modern pragmaticists gathered their inspiration from outside the realm of linguistics proper.

The two streams in this development: an ‘intralinguistic’ one, dealing with descriptive and explanatory questions from a linguistics-internal point of view, and an ‘extralinguistic’ one, emphasizing the social character of the language user and the language used, while insisting on the use of language as a defining feature of pragmatics, often seemed to be on a collision course, yet at other times were able to negotiate a peaceful coexistence. In particular, when one looks at some of the recent developments in pragmatics (some of which the present encyclopedia has only just begun to chart), it becomes clear that the two streams, or tendencies, have much to tell one another. Not only does the ‘purely’ syntactic or semantic approach not suffice, when we are

dealing with typical pragmatic phenomena (such as the manipulative or rhetorical uses of language that ever since the Sophists have been the hallmark of a pragmatically oriented study of language); in addition, the internal contradictions that arose from the desire to create a unified matrix, valid for semantic as well as syntactic description (as, e.g., exemplified in 'Montague grammar') have led to the acceptance of what some have called a 'pragmatic intrusion' into semantics (cf., among others, Levinson 2000: 164 *et pass.*).

For many, the very idea that rules could be given for pragmatic use of language has from the beginning been a *non sequitur*: the creative use of language by the individual in a societal environment could only be circumscribed by the classical, individual-based methods of linguistics, not defined (Mey 2002: 183). Instead, pragmatics has from its very inception promoted the development of society-oriented approaches, that is, approaches that take their point of departure in what is or can be out there, in the social context surrounding us, and then intrapolate these realities and possibilities onto the actual situation in which the language user him- or herself is involved. Such approaches contrast starkly with the well-known efforts by theoretical linguists, traditional sociolinguists, and other social scientists to first define the 'said', and then try to figure out what the conditions are that make a particular utterance 'correct' or 'acceptable'.

In all these cases, there is a certain 'ecological' principle at work, by which users endeavor to maximize their results with minimal efforts, while respecting their linguistic and social environments. This 'ecological turn' has inspired such differing tendencies as, on the one hand, relevance theory, and by what has been called 'default semantics' on the other (cf. Jaszczolt 2005 and the article by that name in this volume). Similarly, we have been witness to the rise of 'optimality theory' in its various versions—this latter approach is still in its infancy and has not yet reached acceptance in most of the 'border territories' (even so, the present work does have an article outlining some notions and possible approaches, cf. the eponymous article presented in the body of this volume).

Other recent developments have resulted in psycholinguistic excursus (or should I say: 'excursions', to remain in the traveling metaphor?). Here, one finds a number of articles dealing with developmental aspects of pragmatics (the psycholinguistic view) or approaches that are oriented towards cognitive psychology (as in 'cognitive pragmatics'). More generally, the cognitive approach itself, originally considered as an extension of epistemic and psychological ways of looking at language use, has come into its own as well, leading to a whole flurry of writings on venerable notions such as metaphor and metonymy, not to forget the return to 'classical', speech act-based ideas—first of all the concept of the speech act itself and its conditions, injecting them with new interpretations of the time-honored Searlean and Austinian conditions and restrictive maxims, including further extended notions, such as that of 'flouting a maxim' (on which see the article of that name, this volume).

The idea that language belongs, not only to a particular culture or country, but also to the speakers themselves, has gained some momentum in the past decades. Thus, the understanding that not everything linguistic is accessible to everybody at all times, and neither to everybody in the same (legally sanctioned) fashion, has given rise to speculations about accessibility in language, and to what has been called 'territory of information'; see, e.g., the article on 'accessibility theory' in this volume, or the writings of Akio Kamio (1994, 1995, 1997) and recent work by John Heritage (2007). To express one's condolences, for instance (to take Heritage's example), presupposes that one has the correct 'stance' in regard to the 'condolee'. More generally, all speech acting on principle belongs to society, and is only derivatively made possible through the language user's active participation in that society—ideas that have been around ever since the eighties (see Mey 1985), and which have lately come to fruition in my theory of 'pragmatic acts' (on which see the article of that name in the current volume; compare also Mey 2008).

The idea that language use and linguistic activities in general (either in the phonetic, syntactic, semantic, or pragmatic realm) obey some kind of 'law of least effort' has been fruitfully mined not only by the protagonists of relevance theory, but also in a more general way by the defenders of optimal, rather than maximal, solutions to linguistic problems. What this means is that rather than abiding by some strict rules (like those that allow one to say 'yes' or 'no' to questions of grammaticality), the thought that an optimal solution often consists in accepting a certain deviation from strict standards has taken hold in the sciences of the human over the past decades.

Early on, the psychologists started to operate with a notion of 'prototype', meaning: a concept with fuzzy edges all around; and in pragmatics, the suggestion that conditions are more optimally construed as constraints on the environment than as production rules binding the individual user, has gained considerable popularity. While a fully fledged theory of 'optimality' is something that we will have to wait (and work) for (as I remarked above), we may observe, at the interfaces between pragmatics and the other linguistic areas, an ever growing trend towards voluntary collaboration, rather than towards unification under some stringent formal umbrella. Given the newness of such approaches, there are only a few articles in the present volume that reflect this

tendency; had there been more time, and had the selection process been less restricted (viz., practically to the original articles in the fourteen mother volumes of 2006), more current work might have been made available.

One issue still bothers the compiler of the present volume, as it did with regard to its 1998 predecessor. It is an issue familiar to all who have ever tried to produce a conspectus-type, work-oriented overview of some area of knowledge. The dilemma of choosing between an alphabetical sequencing of contributions versus an hierarchical, thematically-based division of the field has bothered dictionary and encyclopedia makers for as long as their works have been around. The great *encyclopédistes* of the 18th century, whom I quoted earlier, opted for a strict alphabetical order; while I am not privy to their motivations, I can imagine that ease of access must have been one of them.

One is reminded of the often occurring situation where an opportunistic, ‘seniority’-based order wins out over a logical one for the simple reason that logics are not universal. Compare the nightmare of those medieval philosophers who tried to capture the whole world under one metaphysical hat; closer to home, one needs only to think of the familiar situation where keys and other important items become practically impossible to find because the owner (often identical with the original depositor) no longer is certain which logic has guided his or her movements while putting away the object in question. Most techniques of object (and knowledge) retrieval operate by a logic of local associations: where did I go first, where from there, and so on. The alphabet provides us with an easy to remember, neutral sequence where everything has its place in a mostly universally accepted order; and this logic is what I have decided to follow also in the present volume.

It has been said by the famous Dr. Samuel Johnson (whose doctoral dignity seems to have been more honorific than acquired by hard work) that “dictionaries are like watches: the worst is better than none and the best cannot be expected to go quite true” (in Mrs. Piozzi’s *Anecdotes of the Late Samuel Johnson*). Applying this dictum to the present work and its generic characteristics, one could say that encyclopedias, despite their recognized usefulness, never will achieve the mandate that is inherent in their title, viz. to give a full conspectus of an entire discipline or area of knowledge, let alone of the human knowledge *in toto*.

But even a more modest effort, as represented by the present, concise work, may be useful in giving us the time of day in more than one sense: not just telling us what is going on, but discuss it (through the voices of the articles’ authors) in an intelligent and accessible fashion. If this should happen in the case of the present work, its compiler may have escaped the common doom of all compilers, embodied in the universal tension between that which is attainable and that which should be attained. And with these reservations in mind, I want to give the book my best wishes on its way to the reading public, and say: *I liber* ‘Book, go forth’! May your travel be as happy, and lead to as many interesting encounters, as was the case for the audacious young Englishman, whose peripeties inspired me while I was writing these lines.

Accessibility Theory

M Ariel, Tel Aviv University, Tel Aviv, Israel

© 2006 Elsevier Ltd. All rights reserved.

Natural discourse does not start from scratch. Speakers routinely integrate new information with contextual assumptions, roughly, information that they can take for granted, and so they need not assert it (Sperber and Wilson, 1986/1995). Referring to discourse entities, an inherent feature of human interactions, is no different. Although some discourse entities are (treated as) new (*a kiss* in [1]), most are (treated as) identifiable (e.g., *the review*, *Helen*, *her* in [1], and *her heart*, a first-mention, in [2]). Thus, part of the nonasserted material is information about discourse entities that the speaker would like the addressee to retrieve (for citations of SBC [Santa Barbara corpus], see Du Bois *et al.*, 2000, 2003. [...] = a short fragment deleted):

- (1) LORI: when you were reading **the review**,
 you talked about **the affair between**
 Helen and Paul, [...]
 all that happened was,
LINDA: was **a kiss**. [...]
LORI: **He** kissed **her**, (SBC: 023).
- (2) DORIS: they had an autopsy done on her.
 And **her heart**,
 was just hard, (SBC: 001).

Accessibility Theory (Ariel, 1985a, 1985b, 1988a, 1990, 2001), in effect a development of Sanford and Garrod (1981) and Givón (1983) (and see also Chafe, 1994), assumes a logically prior distinction between identifiable/Given entities (coded as definite) and nonidentifiable/Given entities (coded as indefinite). Identifiable entities are ones for which the addressee is assumed to be able to access mental representations (see Du Bois, 1980; Heim, 1982). Accessibility theory seeks to account for the selection and interpretation of all definite referring expressions. The theory does not assume (as fundamental) the first versus subsequent mention distinction, and provides one and the same account for expressions considered referential (e.g., proper names), often used for discourse first-mentions, as well as for expressions considered

anaphoric (e.g., pronouns), often used for subsequent mentions (Ariel, 1990, 1994, 1996). It also does not view references to the speech situation (e.g., by deictics) as special (Ariel, 1998a). All definite referring expressions in all languages are analyzed as accessibility markers, as instructions to the addressee on how to access specific mental representations. In fact, the theory handles other types of Given materials as well, most notably whole propositions (see Ariel, 1985a, 1985b, 1988b).

Using a definite NP, the speaker signals to her addressee to access some mental representation based either on his encyclopedic knowledge, his awareness of the speech situation, or his discourse model of the interaction so far (Clark and Marshall, 1981). The definite referring expression also provides information about the intended entity, which the addressee is to rely on when zeroing in on the intended referent (e.g., *her* is a singular female). This is as far as the definiteness aspect takes us, but speakers can be even more helpful. Mental representations are not equally accessible to us at any given stage of the discourse. Some are highly activated, others are mildly activated, and yet others, although potentially identifiable, are not currently activated at all. Speakers refer to discourse entities at all activation levels. This is where accessibility theory plays a crucial role. It helps the addressee pick the correct mental representation by indicating to him the degree of accessibility with which the mental representation is currently entertained. The claim is that each referring expression specializes for a specific degree of mental accessibility, hence the term *accessibility markers* for referring expressions. On this view, addressees search mental representations not only based on the content of the referring expression, but also based on the degree of accessibility indicated by the speaker.

Since mental accessibility comes in a rich array of degrees, accessibility markers can be graded on a scale of accessibility marking, some indicating very low degrees of mental accessibility, others indicating various intermediate and high degrees of accessibility. The following partially grammaticized (see Ariel, 2001) accessibility marking scale, starting with very

2 Accessibility Theory

low accessibility markers and ending with extremely high accessibility markers, has been proposed in Ariel (1990), but the list is not intended to be exhaustive:

- (3) Full name + modifier > full name > long definite description > short definite description > last name > first name > distal demonstrative + modifier > proximate demonstrative + modifier > distal demonstrative + NP > proximate demonstrative + NP > distal demonstrative (-NP) > proximate demonstrative (-NP) > stressed pronouns + gesture > stressed pronoun > unstressed pronoun > cliticized pronoun > verbal person agreement markers > zero.

For example, *the affair between Helen and Paul* in (1) is a long definite description. The prediction is that it indicates a mental representation that is not as accessible as the shorter *the review* or *he*. Indeed, *the review* is what the interlocutors have been discussing. But the affair, as such, was not explicitly mentioned in the conversation, and in fact, according to Lori, it's not even clear that there was one. *He* (a pronoun) refers to the highly accessible Paul, who was just mentioned.

Now, the correlations between specific referring expressions and specific degrees of mental accessibility are not arbitrary. This is why (3) is virtually a universal. By and large, the accessibility marking scale is governed by three coding principles: informativity, rigidity, and attenuation. Informativity predicts that more informative expressions be used when the degree of accessibility is relatively low. It is only reasonable for the speaker to provide the addressee with more information if the mental representation is not (highly) activated, so he can better identify the intended entity from among the many he entertains at a low degree of accessibility. Rigidity predicts that a (more) uniquely referring expression (such as a proper name), rather than a relatively nonrigid expression (such as a pronoun), should be used when degree of accessibility is low (cf. *Helen, Paul* with *her, he* in [1]). Finally, attenuation predicts that greater phonological size (including the presence of stress) correlates with lower degrees of accessibility, whereas smaller phonological size correlates with higher degrees of accessibility (cf. definite descriptions vs. pronouns, and even more so with zero).

The three principles overlap to a large extent. Quite often, informative expressions are also relatively rigid and unattenuated. However, this is not invariably so. *The newspaper* and *United States of America* are as informative and rigid as *the paper* and *US(A)*, respectively, but they are not as attenuated. Accordingly, the lower accessibility markers are found in contexts

where a lower degree of accessibility is the case (see Ariel, 2001, *inter alia*). Similarly, in languages with verbal person agreement, there is no difference in the informativity and rigidity between independent pronouns (e.g., Hebrew *ani*, 'I') and the corresponding agreement marker (+*ti* for past tense). But distributional patterns show that the independent pronoun (less attenuated) is used when the speaker is less accessible. Finally, for Western names, it's usually the case that first and last names are equally informative and attenuated, but they are not equally rigid. Last names tend to pick a referent more uniquely than first names (simply because there is a greater variety of last names). Accordingly, Ariel (1990: 45) correlates the two types of names with different textual positions, showing that anaphoric first names mostly find their antecedents within the same paragraph, but last names have three times as many cross-paragraph anaphoric relations. This points to the lower degree of accessibility indicated by last names.

Distance between a previous and a current mention of the entity (recency) is indeed one important factor determining degree of accessibility. Naturally, the longer the time elapsed between the previous and the current reference, the less activated the representation, so that relatively lower accessibility markers are called for. Note that the relationship between the antecedent and the anaphor, their Unity, is not simply measured in number of words (only), but rather, syntactic boundaries (e.g., the clause), textual boundaries (the paragraph, the episode), and pragmatic boundaries (units more vs. less cohesively linked to each other) define the closeness between a potential antecedent and its anaphor, dictating higher or lower accessibility markers depending on how 'distant' the two are from each other. When a discourse entity is inferred based on another, we similarly see differences according to how automatic/stereotypic the inference connecting the two is (cf. *her heart* in [2], which is easily inferred from *her*, given that humans have hearts, with *his sense of character values* based on *his* referring to *Mister Forster* – SBC: 023, where we don't automatically assume that people have a "sense of character values"). Empirical evidence for these Unity claims can be found in Clancy (1980), Sanford and Garrod (1981), Givón (1983), and Ariel (1985a and onward).

Unity features mostly pertain to anaphoric references. Referent salience is important for all types of reference, first-mention referential expressions included. Some discourse entities are inherently more salient: the speaker and addressee (vs. third persons), humans (especially vs. inanimates), and famous personalities (vs. anonymous people). Other discourse entities have a prominent *ad hoc* status, mostly

because they constitute discourse topics. The predictions are then that higher accessibility markers will serve these more salient discourse entities. Competition over the role of intended referent between potential mental representations may, however, lower the degree of accessibility of each, mainly of nontopics. It then calls for lower accessibility markers:

- (4) MARY: What I have to do,
is take off **the distributor wire**,
and splice it_i in with **the fuel pump**
wire.
Because my ... **fuel pump**_j is now
electric, (SBC: 007).

- (5) In the reference, each author is referred to by name and initials. There is a single exception – to avoid the possibility of confusion, first names are always included for **David Payne, Doris Payne, John Payne, Judith Payne** and **Thomas Payne** (Dixon, 1994: xvi–xvii).

In (4), the more topical entity is coreferred to by *it*, the nontopic by an informative lexical NP (*my fuel pump*). In (5), presumably equally accessible entities are all referred to by lower accessibility markers (full names), because they compete with each other (initial + *Payne* is not rigid enough in this context).

It is important to remember, however, that accessibility theory makes claims about correlations between referring expressions and degree of accessibility, measured as a total concept, rather than by any one of its components (e.g., topic, distance, or competition). In other words, the prediction is that accessibility marker selection is determined by weighing together a whole complex of accessibility factors, which together determine what the degree of accessibility of a given discourse entity is at the current stage of the discourse (see Toole, 1996; Ariel, 1999). This is why, for example, even speakers are not invariably referred to by the highest accessibility markers (zero in Hebrew). Although the speaker is a highly salient discourse entity, if she's not topical or if it's competing with another antecedent, it may be referred to by an independent pronoun.

Finally, accessibility theory is universal (see Ariel, 1990: 4.2), although not all languages have exactly the same set of referring expressions, and even when these seem to be identical, they may rate differently for the three coding principles (informativity, rigidity, and attenuation, e.g., cf. English and Japanese pronouns). Provided they are comparable, all referring expressions are predicted to indicate the same relative, though not absolute, degrees of accessibility. Thus, in all languages zeroes indicate a higher degree of accessibility than pronouns, but not all languages

allow cross-sentential zero anaphora. Accessibility theory applies to all genres/registers (see Ariel, in press). In fact, because accessibility related discourse patterns are so common in diverse registers and languages, we can account for various cross-linguistic grammaticization paths. For example, the recurrent creation of verbal person agreement markers for first/second persons, but not for third persons (via the cliticization of the high accessibility markers used for the very salient speaker and addressee; see Ariel, 1998b, 2000), as well as universal constraints on the use of resumptive pronouns (see Ariel, 1999). At the same time, accessibility constraints may be violated to create special pragmatic effects (e.g., *Jamie the old lady* (SBC: 002) is too low an accessibility marker, when used by Jamie's husband in her presence).

Activity Theory

K Kuutti, University of Oulu, Oulu, Finland

R Engeström, University of Helsinki, Helsinki, Finland

© 2006 Elsevier Ltd. All rights reserved.

Cultural-historical activity theory (CHAT) is a school of thought concerning itself with the relation and interaction between humans and their material and social environment. Originally a psychological tradition, it has been expanded into a more general, multidisciplinary approach, which is used (besides in psychology) in semiotics, anthropology, sociology, cognitive science, linguistics, and design research. Thus, it would be more suitable to call it a framework, an approach, or a research program. From another perspective, CHAT is one of the few research traditions in human sciences originating in the former Soviet Union that have been able to gain acceptance in the Western research.

Historical Background

Cultural-historical activity theory, CHAT, originated in attempts by psychologists, as early as the 1920s, to establish a new, Marxist-based approach to

psychology. The foundation of Activity Theory was laid by L. S. Vygotsky during the 1920s and early 1930s. (see Vygotskij, Lev Semenovich.) His work was continued by A. N. Leont'ev and A. R. Lurija, who both developed his ideas further and began to use the term 'activity.' (A good historical review of that development can be found in Leont'ev, 1989.) For a Marxist psychologist, who favors a monistic explanation of human mental processes, the Cartesian mind-body dualism is unacceptable. Thus, the starting point of CHAT is that human thinking has both phylogenetically and ontogenetically emerged and developed in practical action and social interaction in the world; there is no separate mind that could be studied in isolation from these actions; significantly, the individual person is thus not a real unit of the analysis of mind. In any such analysis, the purposefulness of actions must be taken into account, and therefore it is necessary to include a minimal context that makes the actions meaningful for the acting subject. This context, typically a purposeful, social system of actions, is called an activity. Certain general principles within this framework include object orientation; mediation by culturally and historically formed artifacts (tools and signs);

hierarchical structure of activity; and zone of proximal development.

Object Orientation

The most central feature of CHAT is that activities are oriented towards a specific object and that different objects separate activities from each other. In this tradition, the concept of object is complex and loaded. Activities emerge when human needs find a way to be fulfilled in the world. The object here is the entity or state of the world, the transformation of which will hopefully produce the desired outcome. An object has, thus, a double existence: it exists in the world as the material to be transformed by artifactual means and cooperative actions, but also as a projection on to the future—the outcome of the actions. The object is not exactly given beforehand, but it unfolds and concretizes in the interactions with the material and the conditions. Being a constantly reproduced purpose of a collective activity that motivates and defines the horizon of possible goals and actions, the ‘sharedness’ of the object is present only in social relations across time and space, as well as embodied in terms of history. Locally, the sharedness of an object is a process of social construction with divergent views and creative uses of cultural and interactional resources. Activities are thus often multivoiced, and none of the existing perspectives on the object can be defined as right—such a definition can only be given within an activity.

Mediation

The notion of tool mediation is one of the central features of CHAT. Actions are mediated by culturally and historically constituted artifacts, an artifact being defined as something that has been manufactured by a human. Thus, our relation with the world is shaped not only by our personal developmental history and experiences from various interactions, but also by the history of the broader culture we are part of. The world has been concretized in the shape of tools, symbols, and signs that we use in our activities. The world does not appear to us *as such*, uncontaminated, but as a culturally and historically determined object of previous activities. Humans project both these earlier meanings and those that have arisen from the fulfillment of current needs on to their objects; at the same time, they envision the potential results to be achieved. (see **Cognitive Technology**.) Language is an essential part of this toolkit, a tool of tools. According to CHAT, all mediation has both a language side and a material character: symbols and signs, and tools and instruments are all integral

Figure 1 A model of the basic mediational structure. (S) subject, object (O), and medium (M) at the vertices of the triangle indicate the basic constraints of mind. The line S-O represents the ‘natural,’ (unmediated) functions; the line S-M-O represents the functions where interactions between subject and object are mediated by auxiliary means. St_n is the subject’s state of knowledge at time n ; O_{sm} is the object as represented via the medium; O_n , object at time n ; St_{n+1} , emergent new state of the subject’s knowledge at time $n + 1$ (Cole and Engeström, 1993: 5–7). Reprinted from Salomon (1993), *Distributed cognitions*, Figure 1.2, with permission from Cambridge University Press.

parts in the same mediation process. The basic mediational structure is depicted in **Figure 1**.

Thus the foundation of our actions is a continuous synthesis of two versions of the world: one directly given, the other culturally and historically mediated. Their synthesis enables us to plan our actions.

The Socio-Pragmatic Nature of the Sign

Activity Theory has paid much attention to semiotic mediation. Vygotsky’s final work *Thought and Language* (1934) has contributed greatly to the understanding of human mental activity in socio-cultural terms, by assigning a crucial function to language as a psychological tool capable of mediating the development of the mind. Language as a tool calls for the use of artificial stimuli, that is, the use of culturally and historically construed sign systems. Signs serve to control the psyche and behavior of others and the Self, bringing to bear traces of social activities and social relations sedimented in language.

Vygotsky’s socio-genetic approach to thought and language was developed originally in the research tradition of developmental psychology, aiming at understanding the child’s mental growth. Later works of CHAT have continued with semiotic mediation and identity formation by focusing more on language use and utilizing notions such as the internal and external dialogicality of discourse. (see **Addressivity; Dialogism, Bakhtinian; Discourse, Foucauldian Approach; Discourse Processing**.) The interest is here in analyzing language from the viewpoint of sense-making, as it takes place within the contexts of the complex relationship between pragmatic activity and social processes. Sense-making is viewed as an active,

culturally mediated process within and with which the external world is translated into a conceivable world and organized into objects of activities. Social change of language is explored with the help of developmental trends of sense-making through which new elements of meaning come into our social interests without leaving old meanings untouched.

Overall Structure of Activities

According to Leont'ev (1978), activities have a three-level hierarchical structure. Besides the activity level, which is a particular system of actions, and the action level itself, there is a third level, the lowest one, of operations. Operations are former actions that have become automated during personal development, and which are triggered within actions by specific conditions in the situation. Whereas in actions, there are always planning, execution, and control phases, operations are much more condensed, rapid, and smooth. To become skilled in something is to develop a collection of related operations. Operations are not, however, like conditioned reflexes: if the conditions do not fit, the operations return back to the action level.

In the tradition of the founders of CHAT, new forms for depicting activity have been elaborated. The most influential attempt to model an activity is due to Engeström. In his *Learning by expanding*, he aimed at defining a historically and concretely constituted system that has a timespan and internal transformations of its own. The model is presented in Figure 2.

In Figure 2, the model of individual action in Figure 1 has been complemented to depict the

Figure 2 A model of an activity system (based on Engeström, 1987). The initial mediational triangle of individual actions is expanded to cover the social and cooperative dimension of an activity by adding a community sharing the same object and two new mediational relationships: social-cultural ('rules') between the subject and the community, and power/organizing ('division of labor') between the community and the shared object. The model is systemic in the sense that all elements have a relation with each other, but only the three main mediations are shown for the sake of clarity.

collective activity system. The model looks at the activity from the point of view of one actor, the subject, but the fact that subjects are constituted in communities is indicated by the point in the model labeled 'community.' The relations between the subject and the community are mediated, on the one hand, by the groups' full collection of 'tools' (mediating artifacts) and, on the other hand, by 'rules' that specify acceptable interactions between members of the community, and 'division of labor,' the continuously negotiated distribution of tasks, powers, and responsibilities among the participants of the activity system (Cole and Engeström, 1993: 7).

In an activity, the relation between individual actions and the outcome of the whole activity becomes mediated and indirect. Leont'ev (1978) explained the relation between individual actions and collective activity using an example of primitive hunters who, in order to catch a game, separate into two groups: the catchers and bush-beaters, where the latter scare the game in order to make them move towards the former. Against the background of the motive of the hunt—to catch the game to get food and clothing material—the individual actions of the bush-beaters appear to be irrational unless they are put into the larger system of the hunting activity.

Zone of Proximal Development

Activity systems are socially and institutionally composed entities exhibiting internal conflicts which develop through transformations. The characteristic feature of CHAT is the focus on such changes; it studies cognition, including language, as a dynamic, culture-specific, and historically changing phenomenon constituting activity systems. In this context, the zone of proximal development (ZPD) has become Vygotsky's most widely referenced notion. It concerns children's learning processes, and refers to

the distance between the actual developmental level as determined by independent problem solving and the level of potential development as determined through problem solving under adult guidance or in collaboration with more capable peers. (Vygotsky, 1978: 86)

Current activity theoretical studies extend from Vygotsky's dyadic pedagogical outline to potential horizons of different activities that will "mature tomorrow but are currently in an embryonic state." In the tradition of developmental work research, Vygotsky's ZPD indicates in outline the distance between present everyday actions and the historically new forms of the societal activity. In Engeström's model, contradictions in activity systems are "structural misfits within or between activities. The new

forms of activity can be collectively generated as a solution to the double bind potentially embedded in everyday actions.” (Engeström, 1987: 174). Contradictions may not be apparent or obvious, and they often appear as problems and disruptions in the flow of ordinary activities. In CHAT, new challenges of scientific concepts are also actively reflected in the ongoing research. Researchers in the areas of cognition and language studies are participating in the current development of discourse-based concepts.

The International Community

An international CHAT research community has been emerging, beginning from the late 1970s. In the early 1980s, there was a series of Northern European CHAT conferences on education; the first international CHAT conference was held in 1986 in Berlin, where the International Society for Cultural Research and Activity Theory (ISCRAT) was founded. This acronym was also the name used for a series of conferences: in Lahti, Finland, 1990; in Moscow, 1995; in Aarhus, Denmark, 1998; and in Amsterdam, 2002. A couple of these conferences have had their proceedings published as a selection of papers (Engeström *et al.*, 1999; Chaiklin *et al.*, 1998). In 2002, ISCRAT has joined forces with the Society of Socio-Cultural Studies (SSCS), resulting in a new society called International Society for Cultural and Activity Research (ISCAR), whose first joint world conference was held in Seville, Spain, in 2005.

From 1994 on, the CHAT-oriented *Mind, Culture, and Activity. An International Journal* has been published by Lawrence Erlbaum.

Adaptability in Human-Computer Interaction

J L Mey, University of Southern Denmark, Odense, Denmark

© 2006 Elsevier Ltd. All rights reserved.

Introduction

In this article, two main themes will be touched upon: first, I will discuss the general topic of humans’ adaptation to computers as tools, and conversely, how the

computer tool can be adapted to human needs; and second, a particular instance of this adaptive process, in which both humans become (more) literate on and through the computer and computers are becoming more ‘human,’ will be discussed under the label of ‘computer literacy.’ In both cases, emphasis will be placed on the cognitive aspects of the problems, as embodied in the metaphors that are current in this particular discourse.

Adaptation and Adaptability

Adaptation

Earlier views on the computer as a tool (e.g., in human problem solving) have concentrated on the problem of *adaptation*: who or which is going to adapt to whom or which? (For a discussion of ‘adaptability’ vs. ‘adaptivity,’ where the latter is defined as a unilateral coercion on the human to conform to the patterns of behavior imposed by the computer, the former captures the necessity of letting the human decide to which degree, and to what purpose adaptation should be practiced, cf. Mey, 1998.)

Even though such efforts have their rationales in the context of computer modeling as it is usually understood, they do not touch upon the basic problem of adaptation, seen as a dialectic process of integrating two independent but interacting systems, the human and the computer (Mey and Gorayska, 1994). The case is analogous to that of perception; here, neither the senses nor the objects can be said, by themselves and unilaterally, to produce a sensation (e.g., of seeing). Perception is always perception of something, and it is always a perception by and in somebody. In the psychologist James J. Gibson’s words, it is a “circular act of adjustment” (Gibson, 1979): “The activity of perception is not caused, nor is it an act of pure will” (Reed, 1988: 200).

An adaptability approach to computing thus endeavors to integrate two systems:

1. the human user, and
2. the computer tool.

In human-computer interaction, the human neither unilaterally ‘acts’ upon the computer, nor does the computer unilaterally prescribe the human some restricted form of activity. Rather, each system adapts to the other; their functional qualities, taken together, are what makes the use of the computer as a tool possible. In Gibsonian terms, tool making and tool using are tantamount to looking for and exploiting “affordances” (Gibson, 1979). To see this, consider the way our adaptation to, and interaction with, computers is characterized by our use of metaphors (see *Metaphor: Psychological Aspects*).

Computers and Metaphors

Like every other human activity, the use of computers has generated its own set of metaphors. We do our word processing using a ‘mouse,’ ‘scroll’ files up and down, ‘chase’ information on the Internet, get ‘lost’ in cyberspace, or trapped in the ‘mazes’ of the ‘web’; and even if we have no idea what we are doing where in cyberspace, it can always be called ‘surfing.’ It’s as if we were hanging out on the corners of our

computational space – what one could call, using a novel metaphor, our ‘cyber-hood,’ our computerized neighborhood.

Among the various metaphors that currently characterize the computer and its use by humans, that of ‘tool’ has been one of the most pervasive. Just as tools help us execute certain activities better and faster, so too has the computer been considered a tool for performing certain operations (such as bookkeeping, accounting, tallying, registering, archiving, and so on) in a better, more efficient, and especially faster way. Among the attributes of this tool that have attracted most attention are, naturally, the ease with which it ‘falls into’ the human hand and routine; by extension, the computer is not even thought of as a tool any longer: enter the invisible, or ‘transparent’ tool (as I have called it; Mey, 1988), to be preferred over other, more visible and obtrusive kinds of instruments. The computer that adapts itself to the human user becomes an extension of the human body; conversely, the adaptable human user will treat the computer not just as any old tool, but rather as a crutch, a ‘scaffolding’ (in Bruner’s terminology; Bruner, 1983), or even as a prosthesis, as we will see below (see *Scaffolding in Classroom Discourse*).

A Case in Point: The Computer as Prosthesis

It has been well known, ever since the pioneering work of people like Carroll (1991), that the tool we use to perform a particular task not only assists us in doing what we have to do, but also changes our understanding of the task itself and of a host of other things related to the task. It may change the very nature of the task altogether. For instance, to cite a classical case, the vacuum cleaner was originally introduced to alleviate and lessen a housekeeper’s boring chores. In the end, it has increased the workload and made the work itself even more boring, because now it had to be performed more often and to a greater degree of perfection. The tool changes the task, and vice versa, in a never-ending “spiral” (Salomon, 1993).

With regard to computers, the tool has frequently been likened to a prosthesis. In the context of our discussion, this has had some profound effects. A prosthesis, one could say, is simply an augmentation of a human capability (either replacing a lost faculty or extending an existing one). But if we scratch this seemingly innocent surface, a host of hidden assumptions and unexpected problems turn up. First, there is the question of the augmentation itself: how far should we go, or be allowed to go, in the enhancing of the human sensory faculties? Using super-powered lenses and telecameras, we can spy

upon the most intimate happenings in the lives of famous people like the late Princess Diana. But even though the majority of readers of the tabloid press would not be without their daily dose of lurid photo-journalism, everybody agrees in condemning the excesses of the paparazzi when their need for media coverage directly or indirectly harms the celebrities they are pursuing, as it happened in the case of Princess Diana's death. "They are going too far," we hear people say. But what exactly is 'going too far' in what essentially is an adaptation of human goals and values to the possibilities of the tool? And how do we decide what is an acceptable limit for this adaptivity? On the one hand, more knowledge is more power; on the other, 'curiosity killed the cat' (and did irreparable damage to some notable humans and their progeny as well, as the case of Adam and Eve amply illustrates).

The Fragmented Body

The tool metaphor of the computer as a prosthesis carries with it yet another drawback. Since prostheses typically target one particular human capacity for augmentation, we come to think of our capacities as individually 'enhanceable.' There are two aspects to this enhancing: one, we consider only the individual agent, without taking his or her larger societal context into account; and two, we enhance single faculties in the individual, without taking into account the fact that these capacities form a unit, a human whole.

As to the first aspect, the societal character of our capacities, consider the 'paradox of success' that Kaptelinin and Kuutti (1999) have drawn attention to: what succeeds in one context may, by its very success, be expected to be a failure in another, seemingly similar environment. Thus, the very fact that, say, a decision-making computer tool has proven successful in the United States may warn us against trying to introduce it into a Japanese surrounding, where decisions among humans are made in ways that are very different from what is common practice in the U.S. (Kaptelinin and Kuutti, 1999: 152).

The other aspect relates to a currently popular notion of human capacities as being 'modularly replaceable.' Just as we are seeing the beginnings of 'surgical engineering,' in which techniques of replacement have substituted for old-fashioned operation and healing procedures, so we are witness to a trend toward substituting and augmenting not only parts of the body itself (such as is done in heart or kidney transplantation), but entire mental functions. A reasoning chip implanted in our brain relieves us from the headaches of going through the motions of filling in the trivial parts of a mathematical proof or a chain of syllogisms. A chip may replace

a person's worn-out or Alzheimer-affected memory capacities. In general, wetware can be replaced by more sturdy and robust electronic hardware, pre-wired to augment specific mental functions, and even tooled precisely to fit the needs of a particular individual. The potential for prosthetic innovations of this kind is virtually unlimited, up to the point where the whole person may end up being 'retooled' electronically (see **Cognitive Technology**).

The Effects of Adapting

Despite these problems, we are not exactly prepared to shut down our machines in the name of a return to basics, a kind of information-age Ludditism. We will have to live with the computer, even if our adaptation to it, as well as its role as an adaptive prosthesis, carries serious problems, generating side effects some of which were not intended. Here, it is useful to distinguish between primary and secondary effects. To take a well-known example, when Henry Ford wanted to put an automobile in everybody's front yard, the primary effect of this 'automotive revolution' was that people were able to travel farther and in ways not imagined before. But the secondary effects, not foreseen by Ford or anybody else at the time, included our adaptation to this new transportation device: our mind-set changed, the automobile becoming our premier status symbol, our 'escape on wheels,' for some even serving as an extra bedroom. In due course, these secondary effects (including the need to build more and more highways, in the process destroying entire rural and urban environments in the name of transportation, creating a new, 'suburban' life style for millions of people, and so on and so forth) were much more important than the simple primary effects in regard to our modes of transportation. The innovative tool re-creates that which it was only supposed to renew: the prosthetic tail wags the human dog.

Another problem with the prosthesis metaphor, when applied to the computer, is that of augmentation. The prosthetic tool, be it a crutch or a pair of binoculars, augments our motor or visual capacities. The notion of augmenting a human faculty presupposes the existence of something which is not augmented, or 'natural.' The trouble with humans, however, is that 'natural' behavior is a fiction; while we do have certain 'innate' functions (the faculty of speech, the ability to walk upright, and so on), these functions cannot be put to work 'naturally' unless we 'initialize' them, break them in socially and culturally. And in order to do this properly, we need tools. In particular, in any learning situation, we need what Bruner called a 'scaffolding': a total learning environment where

the learner is gradually introduced to the next higher level of competency, all the way relying on the availability of physical and mental ‘crutches’. And the more we enhance our human, culturally bound and socially developed functions, the less we rely on those crutches as external prostheses; we internalize the tools by making them part of ourselves, adapting and incorporating them, as it were, to the point where they are both ‘invisible’ and indispensable.

As an illustration, I will discuss the case of the word processor, thus leading into the second part of this article, which deals with the problems involved in computer literacy.

Computer Literacy

The Word Processor

A word processor is basically a tool for enhanced writing. Starting from the early, primitive off- and online text editors (such as RUNOFF or EDDY), modern word processors (such as the latest editions of Microsoft Word or WordPerfect) are highly sophisticated devices that not only help you write, but actually strive to improve your writing – and not just physically or orthographically. Text editors, for instance, will tell you that a sentence is ill formed or too long, or that a particular concept has not been properly introduced yet.

Computerized functions such as these may facilitate the ways in which we produce texts; on the other hand, the texts we produce are in many ways rather different from those that originated in a noncomputerized environment. Here, I’m not talking only about the outer appearances of a document (by which a draft may look like a final version of an article, and be judged on that count), but rather about the ways we practice formulating our ideas.

For instance, if we know that what we write may be disseminated across an international network, or abstracted in a database that is used by people from different walks of life and contrasting ethnic and cultural backgrounds, we will try to express ourselves in some kind of ‘basic conceptualese,’ shunning the use of metaphors and idiomatic expressions, thus sacrificing style to retrievability of information. As Oracle’s Kelly Wical observed, such automated indexing of documents “will encourage people to write plainly, without metaphors . . . that might confuse search engines. After all, everyone wants people to find what they have written” (Wical, 1996; see also Gorayska, Marsh and Mey, 1999: 105 ff.).

In the following, I will examine some of these effects, and inquire into their desirability and/or inevitability.

Why Computer Literacy?

If literacy (no matter how we interpret this term) has to do with people’s capacities for handling ‘letters’ (Latin: *litterae*), then one may ask: What’s so special about the computer that we need to define a special concept called ‘computer literacy’? After all, people have been using the notion of literacy for ages, and there has never been a need to define a special kind of literacy for a particular tool of writing, such as a chisel, brush, or pen. Whereas ‘penmanship’ has become a synonym of ‘high literacy’ (no longer necessarily exercised by means of a pen), nobody has ever felt the need to define ‘typewriter literacy’ in terms other than in number of words per minute: a good (‘literate,’ if you want) typist can do at least 100 words per minute without committing too many errors, whereas a beginner or ‘illiterate’ person only can do 30 or 40 and will have to use a lot of time correcting his or her mistakes. In other words, there must be a difference, but what is it?

Writer and Tool

What makes a difference is in the relationship of the writer to his or her instrument: chisel and hammer, stylus and wax, quill and parchment, pen and paper, keyboard and screen. This relationship has not always been simple and straightforward; in particular, it has been known to influence the very way people write. The ancient Greek scribes who performed their craft in stone didn’t bother to drag all their utensils back to the beginning of the line they just had finished: instead, they let the new line begin where the old one had stopped, only one level lower; thus, the script called *boustrophedon* (literally: ‘the way the [plowing] oxen turn’) came into being, with lines alternating in their direction of writing/reading. The medieval monks who wrote on parchment often tried to ‘recycle’ this precious and hard-to-get material by erasing earlier scripts and overwrite the deleted text, a technique known by the name of *palimpsest*. (By an irony of history, in due course the deleted text often turned out to be more valuable than the overwritten one. Many of the sources for our editions of the classical authors are due to the monks’ parsimonious writing techniques.)

Undoubtedly, the invention of wood (later lead) letter type contributed greatly to the dissemination of written literature; yet, the effects on the scribe were never a matter of reflection. Much later, when the typewriter got naturally to be used for the purposes of office work, personal letters and literary ‘works of art’ still had to be composed by hand, if they were to be of any value. Even in a more practically oriented domain such as that of journalism, it is a known fact that the formidable, in life chief editor

of the Vatican daily *Osservatore Romano*, forbade the use of typewriters in his offices as late as 1948. His journalists had to write all copy by hand and then give it to a typist or typesetter.

The interaction between writer and tool changed dramatically with the advent of the computer. Not only is this writing instrument more perfect than any of its predecessors, but in addition it possesses a great number of qualities enabling people to approach their writing tasks in a different way. Accordingly, 'computer literacy' can be defined as: knowing how to exploit the various new uses to which the 'computer interface' between humans and letters can be put. Let's consider some of these uses.

How (Not) to Use a Computer

Here, I will not discuss the more specialized functions that computer writing has inherited from earlier technologies, merely perfecting but not changing them: bookkeeping and accounting (cf., the use of so-called 'spread sheets'), tabulating, making concordances, automated correspondence, and other office work (e.g., the automatic reminders one gets from one's credit card company or the local utilities services). The truly revolutionary aspect of computer literacy is in the effect it has on the writing process itself, that which earlier was thought of by some as sacrosanct, immune to any kind of mechanical implementation.

One could say that a truly 'computer literate' person is one who composes his or her literary production directly on the computer, without any interference except from the interface itself. This is a bit like composing directly on the piano, except that the keyboard there normally does not retain what has been played on it. In contrast, the conserving function of the computer is precisely what enables writers to enter into a totally new relationship with their tool.

Earlier work, being dependent on the paper medium, had to be meticulously corrected in the text itself, often with great problems of legibility and understanding (scratching or crossing out, 'whiting out,' overwriting, writing in between the lines and in the margins, cutting and pasting, and so on, with multiple versions often canceling out one another, or at least making perhaps better original lines impossible to retrieve). However, the computer allows the text producer to maintain near-complete independence of the material side of writing.

Paper has always been said to be 'patient' in that it did not protest against whatever the author put down on it, suffering great works of art and utterly trivial composition alike to be entered on its impartial

surface. In comparison, the patience that the computer exhibits is not just an inherent quality of the tool: it is transferred to, and located within, the computer 'literate' who knows that Pilate's age-old adage *Quod scripsi, scripsi*, "What I have written, I have written" (John, 19: 22) has been rendered null and void by this new medium. Here, it doesn't matter what is written, for everything can always be reformulated, corrected, transformed, and recycled at the touch of a keystroke or using a few specialized commands. In extreme cases, we even may see the computer generate near-automatic writing (in the sense of the surrealists), with fingers racing across the keyboard and authors failing to realize what's driving them on. Subsequently, the author who checks and goes over the results may often marvel at the 'inventions' that he or she has been guilty of producing, almost without being aware of the process by which they happened.

Perspectives and Dangers

I will conclude this entry by pointing to some of the perspectives that manifest themselves in a considered approach to the problem of adapting to/from the computer/human, especially as they appear in the context of computer literacy. In addition, I will say a few words about the possible dangers involved in the headlong embrace of new technologies (and their implied mental representations and ideologies) just because they are new. First, there is that age-old dilemma (going all the way back to Plato): Is the human just a kind of idealized entity coupled to a material reality ('a mental rider on a material beast of burden')? Or do we conceive of the union of the two in different ways, now that we have better metaphors to deal with these questions (especially the vexing problem of 'which is master': mind over matter or the other way around)?

Mind and Body Conceiving of the computer as a prosthesis may seem to finally resolve that ancient dichotomy: the mind-body split. If anything in the mind can be reproduced on a computer, then we don't need the body at all. Or, vice versa, if the computerized body can take over all our mental functions, why then do we have to deal with a mind?

There are indeed tendencies afoot that seem to advocate this kind of thinking. Some years ago, a book by Andy Clark (1997, frontispiece) proudly announced, in its subtitle, the ability to "put brain, body, and world together again". However, this synthesis is performed strictly on the basis of a computer-as-prosthesis informed philosophy: one describes

the mental functions as (if need be, computerized) modules, united under a common ordering principle or joined loosely in some kind of mental republic, a ‘society of mind’ à la Minsky (1986), where the different mental functions, conceived of as semi-independent but jointly organized modules, cooperate to form an organized, governing whole.

In Clark’s model, the emphasis is on the brain, not the mind, the latter being characterized as a “grab-bag of inner agencies.” The “central executive in the brain – the real boss who organizes and integrates the activities” is said to be “gone.” Also “[g]one is the neat boundary between the thinker (the bodiless intellectual engine), and the thinker’s world.” No wonder, then, that replacing this “comfortable image” puts us in front of a number of “puzzling (dare I say metaphysical?) questions” (Clark, 1997: 220–221). Leaving those questions aside in our context, let me briefly explore some possible practical consequences of this ‘dementization,’ when seen as involving a decentralization of the individual’s capacities.

Mind, Creativity, and Control While the acquisition of computer literacy as a condition for employment does not create much of a difference as compared with earlier situations (except for the extra cost and training it involves), the use of the computer in creative contexts represents a true breakthrough in the relationship of humans to their work, especially as regards their ways of creative production and reproduction. The interesting question here is not what the computer does to our hands, but in what ways it affects our mental ability to shape and reshape, to work out a thought, and then abandon it (but not entirely!). It is also in how it allows us to come back to earlier thoughts and scraps of insights that were jotted down in the creative trance, as it were – perhaps recombining these *disiecta membra* with other pieces of thought, all available at the drop of a keystroke. This qualitative change of our relationship with our creative tools is the true computer revolution; it defines ‘computer literacy’ as being qualitatively different from earlier, more primitive, creative and cognitive technologies.

The imminent danger of the spread of computer literacy is, of course, that any Tom, Dick or Emma who can handle a keyboard may consider themselves to be geniuses of writing, thus offsetting the positive effect of increased literacy through this reduction of the computer tool to an instrument of and for the inane and mindless. More importantly though, the danger exists that users, because of the apparent naturalness of their relationship to the computer, start considering themselves as natural extensions of the machine, as human tools. Being ‘wired’ becomes thus

more than a facile metaphor: one has to be plugged into some network, both metaphorically and electronically, to be able to survive in today’s ‘wired’ society. The wireless person just ‘isn’t there.’

To see this, consider the way most people are wired into the mass media of communication: their lives and thoughts are dictated by the media. Whoever doesn’t plug into this immense network of ‘infotainment’ (information and entertainment), is ‘out,’ is an ‘outsider,’ in the strictest sense of the word; outside of the talk of the day at the workplace, outside of the discussions in the press, outside of the newscasts and television reports on current scandals and shootings. An ‘insider,’ on the other hand, does not (and cannot) realize to what extent the simple presence of thought and feelings, otherwise considered as ‘naturally’ arising within the mind, is due to his or her ‘wiredness,’ his or her connection to the networks. It takes the accidental ‘black screen’ (or some other temporary media deprivation) to make one fathom the depths of one’s dependency, the extent of one’s being ‘hooked up’ to the infotainment universe (and as a result, being ‘hooked on,’ not just ‘wired into,’ that universe).

‘Big Brother’ and the Mind’s ‘Holding Company’

A final issue is of a subtler, less technical, and for that reason all the more threatening, nature; it has to do with the nature of the mental prosthesis that the computer represents. The computer’s special features (programs and functions that are distributed throughout the hardware rather than being encapsulated in neat, identifiable blocks of instructions, routines being divided into subroutines to be used independently and/or recursively, and so on) have led some of us to think of the brain as a similarly organized, distributed architecture (like Minsky’s “society of mind,” mentioned above). In particular, the currently popular ‘connectionist’ view of mental processing is based on this analogy; the prosthesis metaphor, if applied within this frame of thinking, transforms the individual mental features and functions into a set of independent, yet connected components (what Clark irreverently called a “grab-bag of inner agencies”; 1997: 221). The question is, and the problem remains, how to orchestrate all those brainy agencies into some kind of mental unit(y). For all practical purposes, one could replace the media outlets by some central instrument, have it wired directly into people’s heads, and bingo, we’re in business: the wired society becomes a frightening reality, with ‘Big Brother’ embodied in a central ‘Holding Company,’ a monster computer, controlling and directing our entire lives (cf. Big Brother and the Holding Company, 1968).

One frequently hears computer users employ expressions such as, “The computer is in a bad mood today” or “The computer doesn’t want to cooperate”; one sees irritated users kick their machines, pound their keyboards, or scream at their screens, accusing these devices of lack of cooperation. Such expressions, when they are not caused by either the user’s poor computer literacy, or by a particular hardware or software deficiency, may reflect either a lack of critical awareness of the computer’s properties as an auxiliary tool, or a failure to distinguish between the respective roles of the partners in human-computer interaction and cooperation. The future of human computer interaction lies in the humanizing of the tool, not in the humans’ becoming more tool-oriented and tool-like. And as to adaptation and adaptability, I repeat what I said earlier: the computer tail should never be allowed to wag the user dog.

Addressivity

G S Morson, Northwestern University, Evanston, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

‘Addressivity’ (*obrashchennost’*) is a term coined by the Russian scholar Mikhail Bakhtin as part of his critique of traditional linguistics. It figures as well in the thinking of Bakhtin’s colleague, Valentin Voloshinov, and it is helpful in understanding the approach to language and the psyche taken by

Lev Vygotsky (*see* Voloshinov, Valentin Nikolaevich; Vygotskij, Lev Semenovich).

Bakhtin’s work on language is best understood as part of his more general project to rethink the basis of the humanities and social sciences. Initially trained as a literary scholar, Bakhtin sought to reconceive the nature of ethics, psychology, literature, and language in such a way that choice, unpredictability, and open time were properly acknowledged. His work is suffused with the sense that the study of culture cannot be a science in the hard sense, a view that sets

him apart not only from his Marxist contemporaries but also from numerous schools since the 17th century. Because Bakhtin believed that human thought takes place primarily in the form of inner speech, a new understanding of language proved essential to his larger project of humanizing the 'human sciences.'

Bakhtin reacted to the beginnings of formalist and structuralist linguistics, which he understood as methods of understanding human speech as an instantiation of rules. In this model, the linguist studies the rules, *langue*, and regards individual speech acts, *parole*, as entirely explicable in terms of the rules (*see Principles and Rules*). This model and its attendant assumptions seemed to Bakhtin to exclude not only all that we think of as pragmatics and the social aspects of language but also everything that is truly creative in any dialogue between real people. Bakhtin wanted to formulate an alternative model that treated language, thought, and action as capable of genuine 'surprisingness' (*see Conspicuity*).

To this end, Bakhtin distinguished between sentence and utterance. The sentence is a unit of language understood as structuralists do. It does not take place at any specific point in time, and so is repeatable; the same sentence may be spoken on different occasions. The utterance, by contrast, is a specific act of speech that someone says to someone else on a specific occasion, and its meaning depends in part on the occasion. Each occasion is different, and so utterances are never repeatable. The utterance is a historical event and is part of a dialogue. Sentences provide resources for an utterance, but the utterance requires more than the sentence. Linguistics properly conceived should deal with utterances as well as sentences, but so long as language is understood in terms of sentences, we should call the discipline that studies utterances 'metalinguistics.'

What utterances contain that sentences do not is addressivity. Utterances are constituted by the fact that they are part of a specific dialogic exchange. Addressivity denotes all those aspects of the utterance that make it dialogic in the deepest sense (*see Dialogism, Bakhtinian*). Sentences contain only the potential to mean something, but utterances actually do mean something. In Bakhtin's terms, sentences have meaning (in Russian, *znachenie*) in the sense of dictionary-and-grammar meaning, but utterances have *smysl* (roughly, sense, or meaning in a real context).

One cannot solve the problem of context by writing a grammar for it. Although one can say many general things about context, no grammar of context could ever fully specify it, because context is as various as human purposes, which are irreducible to a set of

rules. No matter how many helpful rules one may devise, there will always be a 'surplus' (*izbytok*). Bakhtin uses the same term, 'surplus,' to describe that aspect of human beings that is left over after all conceivable causal explanations have been applied. One's true selfhood begins where all possible categories and causes have been exhausted. In selfhood, the 'surplus' constitutes our humanness, and in utterances it constitutes the manifestation of humanness in language.

Addressivity involves everything that takes the resources of speech – dictionary meanings, grammar, syntax, rules of context – and turns them into an utterance. In practice, Bakhtin's work involved specifying features of context that were left out by structural linguistics, and so it overlaps strongly with pragmatics. It would be possible to absorb many of Bakhtin's insights into pragmatics without accepting his view of humanness, indeterminism, and the surplus (*see Pragmatics: Overview*).

Consider, for instance, the telegraphic model of language in which a speaker, intending to convey a message, instantiates the rules of language to produce a sentence. In that model, the message is then sent out through a medium to a listener, who decodes the sentence and so recuperates the original meaning. Speaking is encoding, and listening is subsequent decoding. The first problem with this model, in Bakhtin's view, is that nothing in this description would change if the listener were asleep, absent, or entirely different. But in real exchanges, the listener does not passively decode. Understanding is an active process in which the listener not only decodes, but also imagines how the utterance is meant to affect him or her, how it responds to past and potential utterances, and how third parties might respond. With all these factors in mind, the listener prepares a response that is revised as the utterance is being heard. Understanding is personal, processual, and active. Because every speaker counts on understanding of an active sort, the listener shapes the utterance from the outset. Speakers formulate their utterances with a specific listener or kind of listener in mind. This anticipation of a listener, which in ordinary speech is often guided by responses we sense as we are speaking, alters the tone, choice of words, and style of each utterance as a work in process.

Except in the purely physiological sense, each utterance is a co-creation of speaker and listener. It is essentially joint property. Bakhtin offers a series of examples, drawn from Dostoevsky's novels, of utterances whose whole point and stylistic shape would be missed without considering addressivity. In 'the word with a loophole,' for instance, the speaker deliberately exaggerates a self-characterization so that, if the response is undesired, the utterance allows

him to pretend after the fact that it was parodic or unserious. The utterance builds into itself future utterances to more than one possible response.

Such utterances are not only common in daily speech, but also figure in our psyche. Because thought largely consists of inner dialogues, our minds are composed of the listeners that inhabit us – our parents or other figures whose responses count for us. We address them when we think, and so our very thought is shaped by imagined anticipated responses. We justify ourselves, or guide our thoughts by what significant internalized others might say. We grow and change as we absorb new listeners or learn to address old ones differently.

Within and without, we live dialogically. Addressivity, the dialogue of inner and outer speech, involves not only the ‘second person’ (the listener) but also what Bakhtin calls the ‘third person.’ In different studies, the term ‘third person’ has two distinct meanings, both of which are essential to addressivity. Sometimes the third person refers to all those who have already spoken about the topic in question. No one speaks about anything as if he or she were Adam, the first to break the silence of the universe. Every topic has been ‘already spoken about’ and the words referring to this topic implicitly ‘remember’ the earlier things said about it and the contexts in which they were said. It is as if words have glue attaching to them the evaluations and meanings of earlier speakers. Thus, when we speak, we implicitly take a stand in relation to those earlier speakers, and our words may be spoken as if with quotation marks, at a distance, with various tones indicating qualification. Some words come already ‘overpopulated’ with earlier utterances. Our speech therefore contains implicit elements of reported speech (direct or indirect discourse) in which the framing utterance takes a stance with respect to the framed one. Such effects may not be visible in the words when viewed as parts of a sentence, but they are nevertheless keenly sensed by speaker and listener. We are in dialogue with our predecessors, and addressivity refers to this historical aspect of utterances as well as to the present speaker-listener relationship. Whether we are considering the second or third person in addressivity, the utterance is shaped by others.

A second sense of ‘third person’ refers to what Bakhtin calls the ‘superaddressee’ (*nadadresat*). We never turn over our whole selves to a listener, because we cannot count on perfect understanding. Each utterance is partially constituted by the projection of an ideal listener, an invisibly present third person who would understand perfectly. We sometimes make the superaddressee visible when, in talking with one person, we gesture, as if to say, ‘would you just listen to him!’ But visible or invisible, the superaddressee is

part of every utterance. The superaddressee may be personified as God or imagined as the voice of history, but strictly speaking it is a constitutive factor of the utterance itself. We implicitly address this perfect listener as well as the real one before us. The superaddressee also figures in our inner speech, where again it may be personified.

The idea of addressivity allows Bakhtin to analyze a series of utterances that may look linguistically or stylistically simple but that are in fact complex when we consider them as part of a dialogue. Imagine a conversation in which one speaker’s voice has been omitted but its intense effects have left their mark on the other speaker’s utterance: some speech is shaped as if that process had taken place, as if it were one part of a tense exchange. Such speech takes ‘sidelong glances’ at the other’s potential answer and may almost seem to cringe in anticipation of a response. Utterances may be ‘double-voiced,’ so that they seem to emerge from two speech centers simultaneously, each commenting on the other and addressing themselves to a third party. In extreme cases, such utterances may bespeak psychological disturbance, as in Dostoevsky. But double-voicedness also appears in simple form in parody. A vast variety of discourses become visible when we consider them from the perspective of addressivity (*see Narrativity and Voice*).

In contrast to such movements as ‘reader reception’ theory, Bakhtin sees the listener’s response as active, not just after an utterance is made, but also while it is being made. Bakhtin is attentive to the formulation of an utterance as a shifting process. An utterance may change in the course of being said – in response to others, to circumstances, or even to the sound of itself. We are ourselves one listener of our speech acts, impersonating potential others. Bakhtin regards a culture’s forms of addressivity as constantly changing in response to circumstances and the creativity of individuals. Some typical forms of addressivity may coalesce into speech genres, and to learn a language involves learning those genres. Speech genres differ from language to language and change over time (*see Genre and Genre Analysis*).

For Bakhtin, the idea that utterances may change as they are being made suggests that addressivity presumes a speaker truly ‘present’ and ethically ‘responsible’ (literally ‘answerable’ in the original Russian) for what he says and a listener present and responsible for how he listens. As speakers and listeners, we choose and may be held accountable for our choices. Nothing is already made or entirely explicable in terms of pre-given codes or prior causes. Thus, the concept of addressivity is closely connected with Bakhtin’s insistence that ethics can never be a mere instantiation of rules; each situation requires real

presence and judgment. In what we do as in what we say, we really accomplish something never done before. Or as Bakhtin liked to say, there is no 'alibi.' These broad implications of addressivity explain why its pragmatic aspects belong to Bakhtin's project of altering 'the human sciences.' He describes human beings as social to the core because even in our psyche we think by dialogue. Conversely, he describes society and language as possessing both surprisingness resulting from the creative aspects of each dialogue and ethical significance resulting from our answerability for each utterance with addressivity.

Anthropology and Pragmatics

W Koyama, Rikkyo University, Tokyo, Japan

© 2006 Elsevier Ltd. All rights reserved.

Introduction

To see how anthropology and pragmatics are interrelated, we may start with the following observation: pragmatics concerns, first and foremost, actions and events that necessarily take place in context as actual happenings, that is, sociohistorically contextualized

unique happenings. Such happenings, however, may be seen as tokens of virtual regularities such as action types, event types, or even illocutionary types (*see Speech Acts*). Hence, pragmatics may be approached from two different points of departure, either the sociohistoric context or the decontextualized regularities. This condition has given rise to the two distinct scientific traditions dealing with 'what we do' (i.e., our praxis): either the social science of actions and events, such as sociology and anthropology, or the logico-linguistic science of propositionally

centered regularities of speech acts. Both of these trends originated in (neo)Kantian philosophy (see later); they may be characterized as the pragmatic and the semantic tradition, respectively. Note, however, that the term ‘pragmatics’ is, by historical accident, attached to a branch of the semantic tradition. This tradition includes analytic logic, linguistics, and parts of psychology, anthropology, and pragmatics (e.g., ethnoscience, cognitive linguistics, and the theories of speech acts, implicature, and relevance). In contrast, the pragmatic tradition includes the social sciences, sociology, anthropology, critical philosophy, and parts of contemporary pragmatics such as critical discourse analysis and social pragmatics. In the following sections, the genealogies of these two post-Kantian traditions are elucidated, illustrating how linguistic anthropology is related to pragmatics (*see Critical Applied Linguistics; Critical Discourse Analysis; Speech Acts; Implicature; Discourse, Foucauldian Approach; Pragmatics: Overview*).

The Semantic Tradition

Let us start with the semantic tradition, which harkens back to the critical philosophy of Kant (1724–1804), in which the problematic of ‘language’ and ‘meaning’ still lurked behind that of ‘(re)cognition’ and ‘judgment.’ The return-to-Kant movement of the late 19th century included not only the neo-Kantians in the narrow sense, such as Charles Peirce (see below), but also Gottlob Frege (1848–1925), who launched predicate logic and thereby started to reduce the (neo) Kantian problematic of ‘judgment’ and ‘value’ to questions of logical language (*see Peirce, Charles Sanders; Frege, Friedrich Ludwig Gottlob*). In particular, the notion of judgment, especially that of ‘synthetic’ judgment, became eclipsed by the analytic *Satz* (sentence, proposition), which was split into *Kraft* (e.g., assertoric, imperative, interrogative force) and *Sinn* (propositional content); the latter, again, was subdivided into categories and subcategories that could be characterized in formal-linguistic fashion, such as subject, predicate, and so on. Thus was born modern logic (analytic philosophy), to be pursued by Bertrand Russell (1872–1970), Rudolf Carnap (1891–1970), John von Neumann (1903–1957), and others who studied formally encoded meanings outside the context of language use. Such studies, which later came to include work in Artificial Intelligence, became the main staple of 20th-century Anglophone philosophy. This analytic ‘linguistic turn’ (Rorty, 1967) was also taken by the linguists of that period, especially the formalists of the neo-Bloomfieldian and Copenhagen Schools. Like the logicians, they saw the essence of language,

as well as the essence of the science of language, in formal regularities (rules) and clear and distinct analysis, in a decontextualized environment. Eventually, the trends in logic and linguistics converged and gave rise to generative linguistics, led by Noam Chomsky (b. 1928), who learned neo-Bloomfieldian formalism from Zellig Harris (1909–1992) and logico-linguistic derivation from Carnap. Even granted that Carnap was an empiricist, like Charles Morris (see below) and Willard Quine (1908–2000), whereas Chomsky worked in a rationalist paradigm, these philosophers and linguists represented two sides of the same semantic tradition. Subsequently, with the success of what became known as the Chomskyan revolution, the dominance of the semantic tradition in linguistics and its subfields was confirmed in the 1960s.

Yet, this ‘revolution’ was just an evolution of an earlier condition. That is, in tandem with the advocates of ‘unified science’ such as Carnap and Morris, who tried to integrate all kinds of science on the basis of modern formal logic, using the method of modern physics, the neo-Bloomfieldians had elaborated and advanced a linguistic formalism that was meant to replace the humanistic, cosmographic concerns of philology and anthropological linguistics with the investigation into the formal regularities of language and mechanical analytic procedures. Doing this, they successfully turned linguistics into a model human science in the eyes of many. Thus, the semantic tradition evolved from logico-linguistics into the more empirical sciences of anthropology and cognitive psychology. As an instance, consider the mid-20th-century flourishing of ethnoscience, which was characterized by mechanical elicitation procedures, with anthropologists trying to identify the semantic categories of fauna, flora, kinship, color, etc., as emically apperceived by natives and etically described by ‘universal’ semantic categories. Eventually, ethnoscientific studies – such as those of color terms conducted by Berlin and Kay (1969), who were originally inspired by the Saussurean/Hjelmslevian formal-structural analysis – yielded to the more empirically oriented ‘prototype’ semantics developed by Eleanor Rosch and her school in the 1970s (cf., Blount, 1995). Similar empiricist orientations gained acceptance even in logic and linguistics; compare the rise of fuzzy logic (or, more generally, multivalued logic) and generative semantics. The three lines then converged to form cognitive linguistics, pursued by George Lakoff (b. 1941), Ronald Langacker (b. 1942), and their followers. Thus, the birth of an empirical semantic science, i.e., cognitive linguistics, which constitutes a branch of pragmatics today, has its origin in the Fregean analysis of decontextualized propositional content (*Sinn*), which gradually, yet increasingly, became accommodated to

the empirical contexts of referential cognition and language use (*Bedeutung*).

But the Fregean legacy includes more. Recall that Frege reduced judgment to sentence, consisting of not only propositional content, but also force. This notion came to the attention of John Austin (1911–1960), a phenomenologically minded translator of Frege's *œuvre* into English (compare Frege's notions of propositional content vs. force with Austin's notions of constative vs. performative and locution vs. per-/illocution) (see Austin, John L.; **Speech Acts and Grammar**). This move led to the emergence of what is often called modern pragmatics, as pursued by John Searle and his followers (formally, this trend can be captured by the expression $F(p)$, where p and F stand for proposition and illocutionary force, respectively). Others, such as H. Paul Grice (cf. 'what is said' vs. 'what is meant') and the post- and neo-Griceans, followed suit (cf. the success of Daniel Sperber and Deirdre Wilson's theory of relevance) (see Grice, Herbert Paul; **Neo-Gricean Pragmatics; Relevance Theory**). Clearly, this post-Fregean trend also belongs to the semantic tradition and constitutes, with cognitive linguistics, its empirical development. Notwithstanding the label 'pragmatics' that is commonly attached to it, this trend is little more than a branch of empirical semantics, inasmuch as it attempts (as do cognitive linguistics and linguistic functionalism) to relate, if not reduce, the meanings encoded in language (i.e., in lexico-grammar: sentence, clause, phrase; words, clitics, and morphemes) to empirical matters such as function, language use, and understanding. This brand of pragmatics thus excludes such contextual phenomena as cannot be transparently related to propositional meanings or grammatical rules; that is, most human practices, which occur contingently and largely independently of linguistically encoded meanings (cf. Mey, 2001).

In this connection, the following three points are worth observing: (1) the grammarians called 'generative semanticists,' such as George Lakoff and James McCawley, found post-Austinean pragmatics useful; (2) Dan Sperber and Deirdre Wilson's (neo)-Gricean relevance theory remains a highly abstract account based on *a priori* assumptions (economy, eufunctionalism, cooperation, and logico-rationalistic computation), while remaining impervious to the contextual and historic contingencies that lie at the heart of matters pragmatic; and finally (3) the current popularity of trends such as relevance theory and cognitive linguistics may be in part due to their eclectic, quasi-pragmatic, and quasi-semantic character, in line with their emergence at the transitional point where contemporary pragmatics is moving from more semantically oriented theories (such as those of speech acts or generative semantics), which are primarily concerned with linguistically encoded

meanings, toward more robustly pragmatic theories, such as social pragmatics and critical discourse analysis, which are primarily concerned with contingent actual happenings in a sociohistorical context (see **Speech Acts; Critical Discourse Analysis; Pragmatics; Overview**).

Thus far, we have seen how the two post-Fregean semantic trends have led to cognitive linguistics and pragmatics. In the following discussions, we follow the genealogy of a nonsemantic, yet truly pragmatic tradition, derived not from Frege, but from other neo-Kantians, such as Peirce, Franz Boas, and Max Weber, and ultimately going back to Kant himself.

The Social-Scientific Tradition of Pragmatics

The genuinely pragmatic tradition, often known as the social sciences, includes anthropology and sociology, the origin of which goes back to Bronislaw Malinowski (1884–1942), Weber (1864–1920), Georg Simmel (1858–1918), Emile Durkheim (1858–1917), Boas (1858–1942), Karl Marx (1818–1883), Alexander Humboldt (1769–1859), and ultimately the Enlightenment philosophers such as the Marquis de Condorcet (1743–1794), Voltaire (1694–1778), and perhaps even the earlier Giambattista Vico (1668–1744). However, the most important figure in the current discussion is Johann Herder (1744–1803), a student of Kant who critically accepted Kant's critical philosophy and, in doing this, launched a metacritique of the latter, especially of its claim to human (and even 'anthropological' – the term is Kant's own) universality. In Herder's view, such alleged universality is no more than an ideology, conditioned by the historic, geographic, and cultural (that is, contextual) factors peculiar to the Idealist philosopher Kant and his times, i.e., the modern era of the German (secularized Lutheran) Enlightenment. Note that the idea of metacritique was already contained in Kant's critical philosophy, which tried to show, at the transcendental (second-order, or meta-) level, the valid limits of all philosophizing, including its own. Herder in turn elaborated on this theme, attacking Kant's claim to universality by appealing to the cultural diversity of the empirical world(s). Since the validity of such a metacritique can be assessed only by actual investigations into the empirical world, Herder's move led to the birth of the modern social sciences, especially in Germany, as attested by the works of Marx, Boas, and Weber, in which various eras and cultures were methodically compared. In so doing, these authors interpretively identified the sociohistoric uniqueness and contingent conditions of particular cultures and periods and demonstrated the historic/cultural limits and relativity of modern western thought and its 'products'

(including the social sciences and their ethnocentric universalism). Such was the underlying theme of Boasian anthropology, to be described shortly, following a brief look at the development of the 'new' science of sociology.

In the 19th century, between Kant's and Durkheim's times, rapid modernization, urban immigration, and capital formation progressed in England, France, and then Germany, leading to the emergence of social problems such as dire poverty, overpopulation in urban environments, and terrifying labor conditions. As the masses came into being in cities, society became a visible entity, to be investigated through demographic, statistical, and analytical means by reformers in the spirit of Henri de Saint-Simon (1760–1825) and scholars such as Auguste Comte (1798–1857) and Durkheim himself, who created a science called 'social physics' (which later became sociology) to measure, analyze, and control (i.e., 'tame') the social problems. Henceforth, sociology would develop around the two axes of Weberian interpretive, historical sociology (see earlier) and Durkheimian functionalist or statistical macrosociology. However, in the Anglophone world, the latter axis was much stronger, compared to the European continent; this can be seen exemplified in the works of British structural functionalism (social anthropology) and in Talcott Parsons's (1902–1979) systemic sociology in the United States. Such was the contextual background of what came to be known, on the one hand, as the sociology of language, practiced by scholars such as Joshua Fishman, Charles Ferguson, and others (cf., Giglioli, 1972), and on the other as, Labovian sociolinguistics the latter squarely belonged to the mainstream Anglophone tradition of structural-functional sociology, giving preference to macro-social facts and regularities over interpretations and microsocial, contingent happenings.

In conflict with the latter tradition, the sociologist Erving Goffman (1922–1982) paved the way for a minute descriptive analysis of the dynamics of discourse at the microsocial level, and thus helped to revive the interpretive sociology of Weber, Simmel, Edward Sapir (1884–1939), G. H. Mead (1863–1931), and the Chicago School of sociology, known for its ethnographic and symbolic-interactional approaches (cf. Blount, 1995). This revival, often called the 'hermeneutic turn,' came to put its mark on various social sciences, including cultural anthropology, where Clifford Geertz (1926–2006), in the mid-1970s, successfully criticized the semantic orientation of ethnoscience (see earlier) for its neglect of interpretation and context. Similarly, in sociology, the phenomenological movement developed in the wake of the German sociologist Alfred Schutz's (1899–1959) works represented a long-awaited

renaissance in ethnomethodology, originally advanced by Harold Garfinkel (b. 1917), who tried to base the entirety of sociology on the microsocial phenomena of lived worlds, especially their everyday interpretations and dynamic contextualization. Yet, the positivist standard of formal rigor and the phobia of interpretive ambiguity in sociology were such that ethnomethodology quickly lost its contextual flexibility, critical reflexivity, and comprehensive scope, and underwent formalization and miniaturization, thus turning into an independent sociological practice, namely, conversation analysis. This school (often thought to be associated with pragmatics) subsequently incorporated some of Goffman's insights and ideas of post-Fregean pragmatics, as evidenced in Penelope Brown and Stephen Levinson's types of conversational activity and theories of polite behavior (considered as face-maximizing rational decision-making). These theories, due to their eclectic nature, enjoyed popular acclaim especially during the transitory phase when modern pragmatics moved from the semantic to the social-scientific tradition, i.e., in the late 1970s and early 1980s (see **Activity Theory; Face; Politeness**).

The preceding discussion outlines a general genealogy of the microsociological theories of pragmatics. Yet, as regards the crux of the social-scientific tradition, which can be said to lie in the exploration of the sociocultural mechanisms by which language contextually indexes power relations, authorities, and identities, it is missing in most of these theories. In contrast, there are Goffman's microsocial analyses of interaction ritual, frame, and symbolic self-presentation later incorporated into the French sociologist Pierre Bourdieu's (1930–2002) macrosocial theory of 'reproduction through habitus,' the field of practice, and symbolic capital. In Britain's class-stratified society, Basil Bernstein (1924–2000) also struggled with this problematic, especially when it came to determining the role that language plays in formal education. These three figures thus anticipated the coming of a truly social-scientific kind of pragmatics, i.e., critical pragmatics, as pursued in the 1980s by social semioticians, by Norman Fairclough and his Lancaster School, and others, such as Mey (1985, 2001), whose works share more and more traits with the paradigm elaborated by the anthropological tradition (see **Codes, Elaborated and Restricted**).

Although the above-mentioned groups have distinct genealogies, networks, and theoretical foci, all of them are nonetheless actively engaged in the social critique of language in education, medicine, and other kinds of controlling social instances; they also share among them many sources of critical inspiration and much theoretical weaponry, including the works of Peirce, Boas, Sapir, Benjamin Whorf, Roman

Jakobson, Dell Hymes, and John Gumperz in North America (see later), as well as the traditions embodied in the writings of Malinowski, J. R. Firth, M. A. K. Halliday, Raymond Williams, E. P. Thompson, and Stuart Hall in Britain; Émile Benveniste, Roland Barthes, Louis Althusser, Jacques Derrida, Michel Foucault, and Gilles Deleuze in France; Marx, Weber, Theodor Adorno, Walter Benjamin, and Jürgen Habermas in Germany; Antonio Gramsci in Italy; and Mikhail Bakhtin and Valentin Voloshinov in the former Soviet Union. All of these traditions can be seen as unified from a social-scientific perspective, focusing on language use as discourse, i.e., language in social context, and seeing pragmatics, located at the core of language, as praxis, involving social conflicts, power struggles, and identity (re)formations (see Austin, John L.; Foucault, Michel). And, if pragmatics is worthless unless it is concerned with contextualized linguistic practice, that is, with what is done by peoples and individuals living in particular societies and particular times – i.e., not just with ‘what is said’ (linguistic meaning), but with ‘what is done’ in a contextually situated, sociohistorical practice – then a genuine pragmatics must be a social science of praxis, of actions and events in culture, society, and history. Such a pragmatics has been emerging since the 1980s; it erases the disciplinary division between linguistic anthropology and pragmatics and enables seeing classic, post-Austinean pragmatics as a transitory phenomenon in the historic drift moving from the semantic tradition, or the logico-linguistics of decontextualized regularities, toward the genuinely pragmatic social science of contextualized actions and events (see **Pragmatic Acts**).

In the following sections, we take a genealogical look at the North American ‘cosmographic’ school of linguistic anthropology, starting with Boas, in order to get a better idea of the social-scientific tradition, where, if the current drift continues, the future of pragmatics lies. We start out with Peirce, the neo-Kantian whose semiotic Pragmati(ci)sm was comprehensive enough to bridge the gap between the Fregean semantic and Boasian anthropological traditions, as witnessed by Jakobson’s (1896–1982) synthesis of the two trends under the rubric of Peircean semiotics (see Jakobson, Roman).

Pragmatics, Pragmati(ci)sm, and the Social Semiotics of Praxis

As is well known, the term ‘pragmatics’ has come from a tradition that is located in between semantics and social science, namely, American Pragmati(ci)sm. In Charles Morris’s (1901–1979) triadic formulation, we speak of syntax (form), semantics (meaning),

and pragmatics (context) – terms that are derived from the semiotic Pragmati(ci)sm of the neo-Kantian Peirce (1839–1914) and thus properly indicate the origin of pragmatics as being located in Kant’s second *Critique*, or more generally, in the latter’s critical philosophy.

Peirce, who shared much with other neo-Kantians (such as the phenomenologists), articulated what he called a semiotic ‘phaneroscopy’ (phenomenology), in which actions and events constitute the basis of knowledge, aesthetics, and historic evolution (teleology). Most importantly, actions and events are signs that point to objects in context, such as agents (stimuli) and experiencers. Therefore, the basic mode of signification is indexicality, which is based on the principle of contextual contiguity; the other empirically oriented mode of signification, iconicity, is based on the principle of contextual similarity between signs and their objects. In addition, there are empirically unmotivated, albeit contextually indexed and/or iconically signaled, kinds of signs, i.e., symbols; these comprise conventional ideas (ideologies) and denotational codes, as they are presupposed by the speech participants involved in actions and events. These three kinds of signs interact with one another to constitute the human cosmology, as it is anchored on the (inter)actions and events taking place at the *hic et nunc* of human activity.

Eventually, this cosmographic theory of signs was adopted by Jakobson, who, in his comprehensive theory of communication (cf., Jakobson, 1990; Lee, 1997), articulated the empirical, indexically anchored universal matrix of grammatical categories and distinctive features, envisioned as the systematic interlocking of symbolic (formal and semantic) *langue* and indexical (phonetic and pragmatic) *parole* (see Jakobson, Roman). The Jakobsonian legacy successfully integrated Peircean semiotics and Boasian linguistic anthropology; it has been the guiding thread of North American linguistic anthropology ever since, from Hymes’s ethnography of speaking all the way to Michael Silverstein’s social semiotics (cf. Blount, 1995). In the beginning, however, there was Boas, to whom we now turn.

The Genealogy of Linguistic Anthropology: The Boasian Cosmographic Tradition

We now try to reconstruct the cosmographic theories due to Boas, Sapir, and Whorf; these early 20th-century theories have become somewhat obscured by the hegemonic dominance of the semantic tradition in linguistics and anthropology, which gained strength in mid-20th century.

As already noted, like Peirce, Boas was a neo-Kantian who had come to understand the human mind in terms of the three processes of similarity, contiguity, and abstraction, in close resemblance with the Peircean triad of iconicity, indexicality, and symbolicity. Unlike Peirce, however, Boas was a social scientist who fought evolutionism and institutionalized racism. In these efforts, he undertook the task of showing the existence of grammatical structures in every known language, especially (Native) American languages, and used his findings to prove the universality of a symbolic “faculty of forming abstract ideas” (Blount, 1995: 26), common to all human beings. In the process, Boas moved on to empirical studies of diverse languages in a universal framework, including hypothetical universal grammar.

Boas came close to discovering the notion of the phoneme, which harkens back, via the German *Völkerpsychologen* such as Heymann Steinthal (1823–1899), to Wilhelm von Humboldt’s (1767–1835) idea of *innere Sprachform* and, ultimately, to Kant’s notion of ‘the inner and formative power of life forms,’ as he articulated it in his third *Critique*. Coming to the cultural, idiographic, or cosmographic sciences (in the sense of Alexander Humboldt) such as geography, anthropology, and linguistics, from a background in nomothetic sciences such as (psycho)physics and experimental psychology (cf., Stocking, 1996: 9–16), Boas was naturally impressed by the diversity of human phenomena he observed in culturally and historically situated contexts. He saw the two kinds of sciences as being connected via the faculty of categorical perception, i.e., the human capacity and tendency to impose categorical forms (such as sound patterns) on empirical substance or diverse unique (idiographic) phenomena (such as phones and sensations). In this, Boas anticipated 20th-century structuralism, phenomenology, and Gestalt psychology, and their practitioners, whose battle-cry against 19th-century positivists’ preoccupation with sensations was precisely ‘the primacy of (categorical) human (ap)perception.’ Moreover, and perhaps more importantly, Boas (as did the later structuralists) maintained that linguistic perceptions were decisively conditioned by the unconscious structure of the mind; moreover, this unconscious structure could, no less importantly, be rigorously investigated using a set of techniques not uncritically adopted from the physical sciences, in what came to be called ‘structural analysis’ (cf., Boas, 1989: 72–77; Sapir, 1949: 166).

Boas understood categorical phonemic perception essentially as a linguistic, structurally and unconsciously conditioned distortion in the conscious perception of phonetic and pragmatic (i.e., empirical) phenomena. In his critique of logico-linguistic reason (of the kind earlier articulated by Herder and

Max Müller (1823–1900), and later by Ludwig Wittgenstein (1889–1951)), Boas made a critical empiricist departure from the Cartesian understanding of the mind, centered around the conscious reflection that rationalists considered to be the key to reality and verity. Boas stressed the value of empirical data (i.e., phonetic representations and unadulterated texts), gathered through fieldwork, as being critically important to his effort to show the relativistic plurality of cultures and the invalidity of the *a priori* armchair theories of Eurocentric universalism and rationalism, especially evolutionism (cf., Stocking, 1982: 195–233, 1996: 215–256).

Boas indeed was able to show that similar processes of rationalization underlay both evolutionist reasoning and what was called the primitive, ‘savage mind’ (cf., Lévi-Strauss, 1962), and hypothesized that such pragmatic processes of conscious rationalization (as opposed to universally valid, logico-semantic reason) were similar across diverse cultures, although their specific contents (which could be empirically investigated through the study of cultural myths and folklore, including modern sciences and philosophy) varied cross-culturally and showed distinct, so-called ‘geniuses’ of peoples. Thus, Boas, as Marx had done before him, understood theoretical reason and consciousness as a veil, or a mirror that produced distorted reflections of empirical phenomena such as cultural practices. For Boas, conscious behaviors distort and change these practices, which are otherwise unconsciously and habitually carried out and historically preserved. It is in this context that Boas underlined the methodological significance of linguistic structure, a largely unconscious phenomenon, which was assumed to provide a crucial key to the historical reconstruction of past practices (see Blount, 1995: 23–26; cf., Sapir, 1949: 432–433; Silverstein, 1979).

It may be useful to further unfold Boas’s argument, in particular as it was later elaborated by Sapir (1949: 26–27, 156). First, both conscious and unconscious elements of the human mind are theorized as essentially reactive in relation to the sociohistorical practices (pragmatics) that are represented by, and give rise to, them. Yet, the agentive awareness (consciousness) of practices is limited, and when human agents act in accordance with such limited and distorted awareness, they precipitate the transformation of these very practices, and history starts unfolding (in Weberian terms, this is the dialectics between conscious ideology, such as Protestant ethic, and actual practice, such as capital formation and labor). On the other hand, the unconscious mind, which comprises linguistic structure, more transparently reflects human practices (at time t_0); but, since practices quickly change, along with consciousness, in a dialectic movement, the unconscious is left

behind (at time t_1), and the correspondence with synchronic practices (at t_1) becomes opaque, even though it remains more transparently related to the diachronically prior practices (at t_0). Therefore, both consciousness and the unconscious (where linguistic structure is mostly located) end up being only opaquely related to synchronic practices. Thus, for Boas and his followers, 'synchronic structure' is both synchronic (inasmuch as it is used 'here and now') and diachronic (inasmuch as it points to past practices). This synchrony is made up of both static and dynamic facets, the former (i.e., linguistic structure) relatively transparently pointing to the past and the latter being 'where the action is' (viz., pragmatics and phonetics); the Weberian dialectic interaction between the two, contingently creates the historic conditions for the structures and actions that are yet to come (see **Phonetics and Pragmatics**). Thus, the discovery of the phoneme (and of linguistic structure in general) was directly linked to the rebuttal of 19th-century neogrammarians' genetico-causal determinism (itself a further derivate of the Newtonian-Laplacean deterministic worldview), according to which the posterior condition is mechanically determined by the anterior, and faultlessly derivable from it. The discovery of synchrony (vs. achrony) also was instrumental in Saussure's discovery of the historic dialectics of *langue* and *parole*, as noted by the dialectician Maurice Merleau-Ponty (1908–1961), who properly stressed the importance of the latter's discovery of *parole* (and, implicitly, of pragmatics).

No less important, given the opacity between structure and practice in the synchronic phase, is the following corollary: from the preceding premises, it deducibly follows that phonetic acts do not transparently match the phonemic categories they correspond to – a mismatch that provides part of the conditions 'distorting' phonemic apperceptions. Similarly, pragmatic acts (say, commands) do not uniquely match grammatical categories (say, the imperative mood, as becomes clear when we study the so-called indirect speech acts) (see **Pragmatic Acts**). In other words, the irreducibility of linguistic structure to pragmatics, a phenomenon that Chomsky sees as having its origin in the human innate faculty of reason, is shown to be deducible as a consequence of historical dialectics, generated by the very limits of consciousness or reason (cf., Sapir, 1949: 100–103). Further, just as phonetic phenomena are misperceived through our unconscious phonemic patterning (which escapes reason), pragmatic practices and referents are often incorrectly apperceived by the native mind due to an unconscious grammatical patterning (that is, due to the language-specific structural pattern found to exist in the morphosyntactic encoding of grammatical categories) (see **Speech Acts and Grammar**).

This is the crux of the argument that has come to be known as the linguistic relativity hypothesis (cf., Blount, 1995: 26–28; Cowan *et al.*, 1986: 455–477; Whorf, 1956: 134–159) (see Sapir, Edward; Whorf, Benjamin Lee).

Examining the linguistic relativity hypothesis requires us to undertake empirical studies of linguistic structures and practices across languages and cultures, which again necessitates the hypothetical construction of universal inventories of structurally significant sounds and grammatical categories (as these indeed were presented by Boas (1911)). Clearly, the typological works of Sapir (1921) and Whorf (1956: 87–101) – as well as Jakobson's (1990) theories of distinctive features and verbal categories, which may be marked 'overtly' or 'covertly' (Whorf, 1956: 87–101) in particular languages – were further elaborations of this non-Eurocentric 'universal grammar,' based on emically significant categories in the languages of the world, and suggesting the possible existence of a universal human reality underlying the particular worlds of diverse cultures (cf., Sapir, 1949: 160–166; Whorf, 1956: 147, 207–232).

The basic framework of the Boasian cosmographic tradition, as it was shared by Sapir and Whorf, became the context in which Sapir's twin notions of drift and psychological reality are to be understood. That is, in contradistinction to the neogrammarians' mechanical, genetico-causal 'blind change,' drift, vaguely and holistically perceived as *Sprachgefühl*, refers to historical structural changes caused by the dialectic interaction between structure, language use, nonlinguistic practice, and metalinguistic rationalization. Sapir, a social scientist, understood that ideal patterns (Sapir, 1921: 147; 1949: 23, 83–88, 533–543) in structure were necessarily realized not in their pure forms, but in contextualized and varied, i.e., idio-, dia-, and sociolectal, form-tokens. Some of these variations may become saliently social-indexical and directly involved in the social struggles for cultural hegemonies, as well as in processes of normative rationalizations. In such cases, the interaction between language and society often results in structural changes (cf., Blount, 1995: 513–550). Also, some of the variations may become privileged when language users feel they are being formally correct, that is, actualizing potential regularities implicitly suggested by the synchronic state of language. In such a case, the variations analogically deducible from the structure's dominant pattern may become part of the structure that will arise from the interaction between language and the *Sprachgefühl* of the language users (cf., Sapir, 1921: 147–191; Whorf, 1956: 134–159; Lucy, 1992). (Sapir hypothesized in addition that such analogies were drawn and actually

implemented because of unconscious human strivings for formal beauty; on this, see below.)

Sapir's (1949: 16, 33–60) 'psychological reality' may be similarly reconstructed in the following way. Sapir (1949: 433) started out from the Boasian thesis that linguistic consciousness was opaque to practices, partly because it was influenced by unconscious structural (sound) patterns. This implies, Sapir noted, that there is some transparent linkage between consciousness and 'inner forms' (the sound patterns). Of course, native language users cannot consciously articulate the structure of their language, but they can 'feel,' half- or sub-consciously, such inner forms, which are beyond the realm of phonetic behaviors directly perceived by outsiders of the linguistic community. In other words, native language users (insiders) 'click with' (Sapir, 1949: 48, 159) the linguistic structure at the intersection of their consciousness and unconscious, i.e., at the level of feelings. And such an inarticulate, yet immediately sensed *Sprachgefühl*, and with it, the unconscious structural patterns, are manifested even in overt linguistic behaviors such as the categorical apperceptions of sounds, actions, and referents (cf., Sapir, 1921: 55, 1949: 46–60, 150–159; Whorf, 1956: 134–159). These attested behaviors would remain unexplained if it were not for the phenomenological reality of the phoneme and other form-patterns in the unconscious. Moreover, Sapir noted that allophones of a phoneme often historically developed into different phonemes. In his view, this meant that phonemic inner forms often transparently correspond to the historically reconstructed phonetic (allophonic) behaviors of users in the past (cf., Cowan *et al.*, 1986: 67–106). In this way, the linguistic history of a community was discovered to be alive (phenomenologically, psychologically real, or 'organic') in the *Sprachgefühl* and innermost unconscious of the language users. The individual mind, in short, is communal and historical in its subconscious core. Hence, Sapir noted, there is no need to oppose the individual to the social (collective), to hypostatize a 'super-organic' collectivity existing independently of individuals, or to reify culture or language.

In Sapir's cosmographic theory, the psychological reality had other important implications for the cultural nature of the human mind. That is, unconscious, historical, and communal symbolic forms are ideologically projected onto the chaotic reality of discursive practices, precipitating the chaotic, rhapsodic, and romantic "flux of things into tangible forms, beautiful and sufficient to themselves" (Sapir, 1949: 348), as they are found in poetically structured discursive texts and rituals. In and by themselves,

the symbolic forms constitute an artwork of classicism, often referred to as 'the poetry of grammar,' created by the human striving for an aesthetic totality, *un système où tout se tient* (compare the notion of drift, referred to previously) (cf., Sapir, 1949: 344; Cowan *et al.*, 1986: 455–477; also consider Jakobson's (1990) 'poetic function'). Thus, in Sapir's view, the very regularity of linguistic structure – a regularity necessary in order to operate with decontextualized denotational and cognitive significations – is constituted by our aesthetic, expressive, and ideological strivings for formal completeness. Cognition, aesthetics, emotion, history, society, and the individual are thus intertwined in Sapir's cosmographic theory.

Unfortunately, the inroads made during the 1940s and 1950s by the semantic tradition into the sciences of language almost altogether eclipsed Sapir's cosmographic science, except in the narrow circle of linguistic anthropologists. This process started with the neo-Bloomfieldians, to be followed by the ethnoscientists in anthropology, the Chomskyans in (psycho)linguistics, and the cognitive scientists of diverse obediences, who all operated in this tradition. Nevertheless, Sapir's students, such as Stanley Newman (1905–1984) and Mary Haas (1910–1996), successfully passed the torch to the next generation, whose representatives included John Gumperz and Dell Hymes, who succeeded in firmly integrating the Boasian and Peircean–Jakobsonian (semiotic) approaches (cf., Gumperz and Hymes, 1986). Subsequently, Hymes's theory of communication, called the 'ethnography of speaking,' gained momentum in the 1970s (cf., Bauman and Sherzer, 1974), a decade that saw the hermeneutic (i.e., interpretive, contextual, or (neo-)pragmatic) turn in the social sciences and Anglophone philosophy (as pointed out previously). This turn provided the historic conditions for a revival of the Boasian tradition in contemporary North American linguistic anthropology, locating language squarely at the intersection of history, ideology, and practice (see Blount, 1995; Brenneis and Macaulay, 1996; Duranti, 2001; Kroskrity, 2000; Lee, 1997; Lucy, 1992, 1993; Schieffelin *et al.*, 1998; Silverstein and Urban, 1996). Here, the historic, ideological, and pragmatic aspects of language, including not only grammar, but also (con)textualization, language change and variation, Bakhtinian voicing, standardization, rationalization, modernization, linguistic nationalism and imperialism, language purism, feminism and gender, literalism, and other cultural ideologies and practices, seen in their sociohistoric context, are cosmographically studied in a social-scientific framework. Their discovery of the (re)formations of group identities and

power relations and sociocultural conflicts as happening in, and being constituted by, language as the central element thus converges with the social drift of contemporary critical pragmatics.

Applying Pragmatics

L F Hoye, The University of Hong Kong, Hong Kong, SAR, China

© 2006 Elsevier Ltd. All rights reserved.

The term 'applying pragmatics' (AP) is coined in this entry in preference to 'applied pragmatics' to signal that AP is a dynamic, user-oriented activity. With a wide and evolving range of applications in the societal context, AP contrasts with the somewhat fossilized term 'applied linguistics', which is primarily associated with (foreign) language learning and

teaching, although it does cover linguistic applications in other areas, such as speech pathology, translation, and lexicography. Applied pragmatics embraces practices rooted in a pragmatic perspective on language users, language use, and contexts of use, where the users and their complex of personal, social, cultural, and ideational contexts are seen as paramount. If pragmatics itself is a 'user-oriented science of language', AP is a problem-solving activity with an emphasis on using pragmatic knowledge critically, imaginatively, and constructively in the real-world context of the 'social struggle', rather than on

rehearsing the tenets of canonical pragmatic theory (Mey, 2001: 308–319).

The relevance of pragmatics for the wider social agenda at the micro- and macro-levels of operation can be attributed in part to a series of developmental and formative tendencies: a concerted reaction to the syntactic formalism of Chomskyan linguistics and the preoccupation with language as system, where the language user and contexts of language use are disenfranchised; a ‘social-critical’ impetus, fueled by the desire to create a socially sensitive practice of language, typified for instance by the work of Basil Bernstein and the critical distinction he drew between restricted and elaborated code; a unique perspective on language as action and speech act theory, initiated by the work of J. L. Austin and the work of ‘ordinary language philosophers’; and a perspective on language as communication rather than on language as grammar, deriving from the ethno-methodological tradition (Mey, 1998: 716) (*see Codes, Elaborated and Restricted; Austin, John L.*).

Levels of Application: Micro- and Macro-processes

Applying pragmatics operates at both the micro- and macro-levels of communication, although this distinction is approximate and more of a labeling convenience, since the two levels interpenetrate and synergize. ‘Micro-pragmatics’ looks at the day-to-day context of communication between individuals and groups situated in their local contexts. At the same time, local practices need to be seen against the societal backgrounds and institutional settings in which they occur (i.e., ‘macro-pragmatics’). Micro- and macro-pragmatics are points in a continuum, each linking to the other and each serving as the focus according to the aim of the enquiry. Verschueren (1999: 220–224) cites Goodwin’s (1994) analysis of the Rodney King trials as a case in point. While being arrested for a traffic violation in Los Angeles, King, an African-American, was subjected to a violent beating by police officers – an event that was filmed by an amateur video photographer and later broadcast on public television to public outrage. The police officers were subsequently put on trial and later acquitted. This led to street riots in Los Angeles and a subsequent retrial. As a communicative event, the courtroom proceedings can only be properly understood in relation to the macro-setting created by the institutional and social contexts in which they took place and through which they were mediated: the particular structure and participant roles and the associated verbal processes typical of the (U.S.) courtroom and a legal/trial setting; the actual and perceived social status of African-Americans within

American society, as embodied by King at the time and subsequently; and the role of community and civil rights leaders and their adoption of the King case as a heuristic to draw attention to racism and police brutality. Thus, transcriptions of the trial process can be initially approached as instances of face-to-face linguistic interaction in a courtroom setting, but as the tale unfolds, the total event and its wide-reaching implications can only be properly understood in terms of how (U.S.) legal institutions reflect, endorse, and perpetuate particular societal practices and values.

Domains of Application: Micro- and Macro-pragmatics

As a perspective rather than a component of a linguistic theory, pragmatics can purposefully be applied in the investigation of all instances of language use, whether at the level of the individual, the group, the institution, or society as a whole, and whether at the level of the sentence/utterance or in relation to extended discourse (Verschueren, 1999: 203; Mey, 1998: 728). With its focus on the sentence/utterance level of discourse, micro-pragmatics is concerned primarily with the local constraints of the immediate context, such as: deixis and the indexing of personal, temporal, and locative features; reference and the textually directive function of anaphora and cataphora; and word order and the sequencing/clustering of particles and their discourse function to modify illocutionary force, to facilitate the management of conversation, or to highlight salient parts in a stretch of discourse (*see Deixis and Anaphora: Pragmatic Approaches; Discourse Anaphora; Discourse Markers*). Yet, rooted as these linguistic features are in the immediate surroundings of an utterance, the link with the world becomes apparent as the focus shifts from the individual to the wider, institutionally and societally driven contexts in which humankind must necessarily operate. To quote Mey (2001: 177):

The world in which people live is a coherent one, in which everything hangs together: none of its phenomena can be explained in isolation.

This is now the domain of macro-pragmatics. Institutional and institutionalized language practices figure prominently on the agenda (and often), where power asymmetries may arise as the result of gender difference, perceived social standing and social privilege, and (lack of) access to power. Typical research areas and domains of application include: medical discourse and the study of language use in doctor-patient interviews, psychoanalysis, and schizophrenic discourse; educational and pedagogical language practices, such as teacher-student interaction, language

acquisition and the development of pragmatic competence, the articulation of language policy in relation to minority language instruction, wording of the learning/teaching curriculum, and, more generally, the sets of attitudes and beliefs propagated through the 'hidden curriculum'; the language of the workplace and its impact on management-worker relations; the language of the media, especially advertising discourse; the language of politics, government, and ideology, viewed as a force for linguistic manipulation and the engineering of human minds; and intercultural and international communication and the (lack of) understanding of cultural and communicative diversity, where what is pragmatically appropriate in the given context is at issue. In short, macro-pragmatics considers language use in terms of the totality of contexts in which the unique, dynamic, human activity of verbal communication takes place. It takes its cues from a variety of other related disciplines, such as (linguistic) anthropology, sociology, ethnology, and linguistic science itself. (see **Institutional Talk; Media and Language: Overview; Intercultural Pragmatics and Communication; Social Aspects of Pragmatics; Language Politics.**)

Applying Pragmatics and the Language User

Applying pragmatics aims to develop an awareness of the crucial role that language plays in the construction of individual, group, and societal identities and the consequences of these 'constructed identities' for individual freedoms and the rights of individuals to participate fully in the communities of which they are a part. Exploration of the macro-context, in relation to which all language activity takes place, is the province of 'societal pragmatics', with its unique focus on the users of language and the prevailing conditions under which they use language. Applying pragmatics highlights problems of language use that arise in social contexts where the failure to communicate successfully may lead to social exclusion and disadvantage (see **Social Aspects of Pragmatics**).

The domain of education is often singled out as the main sphere of human activity in which social privilege and access to power are unevenly distributed. Education is mediated and perpetuated through language. Any departure from institutionally identified standards of linguistic behavior is stigmatized and faces sanction. Hence, talk of linguistic oppression may take place, as evidenced, for instance, by the opposition between 'low' and 'high' prestige dialects. The latter can be associated with the linguistic standards whose observance is dictated for wider use by a minority but dominant class of language user. This language oppression is nothing

less than social control through language. The insights provided by AP enable us to develop an awareness of the insidious effects of language repression while calling for greater transparency in how society deals with the individual's linguistic behavior in the educational setting (Mey, 1998: 731–732) (see **Power and Pragmatics**).

Societal pragmatics is also concerned with other social contexts in which linguistic repression is at work and where individuals behave unwittingly, in a certain way, on account of an institutionalized power imbalance. Medical discourse and the instance of schizophrenic speech are a further case in point. Schizophrenic speech is associated with abnormal language. Such speech impoverishment represents a loss of humanness, because the 'nonlanguage' of the schizophrenic, as it is now defined, has become a symptom rather than a means of communication and thus a target for psychiatric manipulation and intervention. By raising questions about the nature of interactive norms in medical practice, AP can argue the need for informed intervention, where the relationships between humanness, language use, sanity, and institutional power are placed under public scrutiny.

Matters of linguistic diversity and endangered languages are also fertile territory for pragmatic intervention. Language attrition, language loss, and language death are all issues on the pragmatic agenda, where description is seen only as an initial step to corrective action rather than as an end in itself (see **Minorities and Language; Endangered Languages**). Notwithstanding controversies over the global, cultural, political, and historical impact of English on smaller indigenous languages, AP can raise public awareness, help collate data, monitor linguistic policies and practices, seek to influence policymakers, and offer practical and professional support to speech communities actively wishing to preserve their languages. For instance, the Linguistic Society of America records that active intervention in this manner, as opposed to mere description and documentation, has shown highly promising results. Its website records that:

Language loss is [often] far more directly a consequence of intolerance for diversity [than an inevitable result of progress], particularly when practiced by the powerful against the weak.

Applying Pragmatics and the Social Struggle

Applying pragmatics is explicitly concerned with situating the concerns of societal pragmatics in terms of a broad social-political agenda; it is interventionist rather than descriptive in its primary aims. Applying pragmatics is all about doing pragmatics. As a case in

point, Mey (2001: 313–315) cites the success of the linguistic war against sexism and the now mostly abandoned use of generic pronoun *he* as a modest yet significant victory for nonsexist practice. Uprooting the hegemonic *he* is not just linguistic tinkering; it brings about a restructuring of stated social relationships, thereby facilitating gender equality (see **Gender and Language**).

Applying pragmatics shares common concerns with critical linguistics, whose aim is to expose the hidden relationships between social power and language use, against the backdrop of sociopolitical and cultural factors. Case studies include: political discourse, specifically the clichéd rhetoric of Britain's political parties; the language of labor disputes and their documentation in the media; the use of more critically aware pedagogies in (English) second-language teaching; and the characterization of social power as a given or natural phenomenon, legitimized through unquestioning acceptance by the public (see **Media and Language: Overview**).

Applying pragmatics has a crucial, empowering, and emancipatory role to play. It helps us understand the power of language to discriminate indiscriminately across a range of social contexts; it suggests an agenda for pragmatically informed intervention on behalf of the disenfranchised, underprivileged language user; and, last, it seeks to put language in the hands of the language user, wresting linguistic control from those who would undermine and deny the rights and freedoms of the individual (see **Pragmatics: Overview**; **Marxist Theories of Language**).

Austin, John L.

W A de Pater and P Swiggers, Katholieke Universiteit Leuven, Leuven, Belgium

© 2006 Elsevier Ltd. All rights reserved.

Austin was born on March 26, 1911 in Lancaster. After studying philosophy in Shrewsbury and Oxford,

he became fellow of All Souls College (1933) and later professor in Magdalen College at Oxford University, where he remained until his premature death on February 8, 1960. Although he was 'White's Professor of Moral Philosophy,' Austin is especially known for his contribution to linguistic philosophy and for his very personal use of ordinary language philosophy,

which he applied to fundamental issues such as meaning, free will, knowledge, truth, and other minds.

Austin was averse to theory building; he was fascinated by the analytical method of lexicographers, which he used for the study of how words and phrases are used in statements about reality, in the expression of beliefs and intentions, and in all types of conventional talk. Good examples of his philosophical use of the lexicographical approach can be found in his *Philosophical papers* and in *Sense and sensibilia* (in the latter work the foundations of British logical positivism are subjected to thorough criticism).

Austin's lasting contribution to the philosophy of language and to linguistic theory (especially pragmatics) lies in having initiated what later (through the work of his student John Searle) was to become the theory of speech acts. The starting point was Austin's observation (dating back to the 1940s) that there are two essentially different types of utterances: utterances that say how things are (or say what is the matter), and utterances that, merely by being made, bring about something (a 'new reality'). Austin called the former type 'constative' utterances (*The book is on the table*), and the latter type 'performative' utterances (*I baptize you Charles*). Whereas constative utterances are (primarily) judged on their truth/falsity, performative utterances are judged on their felicity/infelicity: their (non)success depends not on what the world is like (precisely because they bring about a new fact), but on felicity conditions, such as: appropriate context, authority and sincerity of the speaker, and the existence of certain (cultural) conventions. This distinction, which is the starting point of the William James Lectures given at Harvard University in 1955 (on 'Words and Deeds'), posthumously published as *How to Do Things with Words*, was then questioned by Austin himself, and replaced, in the course of the lectures, with a larger view on types of utterances, coupled with (semantic-pragmatic) types of verbs and with types of communicative strategies and effects. The final distinction is then one between acts (it would be better to speak of features of linguistic acts, or of power potentials or forces of acts):

Austin speaks of locutionary act (act *of* saying something, with a particular sense and reference), illocutionary act (performing an act – such as warning or accusing – *in* saying something), and perlocutionary act (the act – such as frightening or offending the interlocutor – achieved *by* saying something). As different people may react differently (some are frightened when being warned, others not), the nexus between the perlocutionary force (as yielding an effect in the hearer) and the two other forces is of a non-conventional nature.

Austin did not organize these ideas into a systematic theory, nor did he live long enough to answer the objections soon made to the published version of his lectures, which shows the evolution in his approach of 'words and deeds' and ends with a number of open questions. Thus it was all the more important that Searle turned Austin's gradually revised approach into a comprehensive speech act theory.

B

Bakhtin, Mikhail Mikhailovich

S O'Neill, University of Oklahoma, Norman, OK, USA

© 2006 Elsevier Ltd. All rights reserved.

Mikhail Mikhailovich Bakhtin was born in Orel, Russia, south of Moscow, on November 16, 1895. Coming of age in turbulent times, he attended Saint Petersburg University between 1916 and 1918, dividing his time between classics, literature, and philosophy, while maintaining a keen interest in language outside the classroom. During the 1920s Bakhtin came into contact with Voloshinov and Medvedev, two fellow intellectuals who shared his broad interests in language, politics, dialogue, and literature. Later known as the Bakhtin Circle, these young writers met regularly to discuss the philosophy of language until 1929, when Bakhtin was arrested, detained, and later exiled to Kustanai in 1930. After working as a book-keeper on a collective farm, Bakhtin traveled to Saransk in 1936 to accept a position at the Mordovia Pedagogical Institute, where he taught Russian and world literature until his retirement in 1961. In 1940, Bakhtin submitted his dissertation, *Rabelais and the history of realism*, to the Institute of World Literature in Moscow, for which he was awarded the lesser degree of Candidate of Philological Sciences in 1952, rather than the doctorate. Although Bakhtin was a humble scholar who received little public recognition during his lifetime, his ideas have had an enormous, global impact on the philosophy and sociology of language. Bakhtin died in Moscow, Russia, on March 7, 1975.

Bakhtin is best known for his work on dialogue, a concept he continued to develop over the course of his career. For Bakhtin, dialogue was the central reality of language, a position partly inspired by the Greek philosopher Socrates, who stressed the emergent nature of truth in dialogic exchanges between opposing parties. In Bakhtin's estimation, the most productive exchanges occur between parties that enter into a discussion with contrasting points of view, allowing for change and diversity in society. Bakhtin hinted at this position in his first major publication, *Problems of Dostoevsky's poetics* (1929), in which he praised Dostoevsky for writing 'polyphonic'

novels that represent the many competing voices found in every society. Because these voices resonate with larger systems of thought, such political orientations or even scientific worldviews, Bakhtin maintained that ideology, or perspective, is pervasive in everyday language use.

The political implications of dialogue are greatly expanded in Bakhtin's later writings. In *The dialogic imagination* (1981), he identified two major trends on the ideological plane. One tendency is toward homogeneity, where 'centripetal' forces seek to centralize the perspectives, discourses, or linguistic varieties found in society, reducing diversity and the possibility of change. Taken to an extreme, this monologic tendency leads to the death of dialogue, a fearful possibility that Bakhtin personally experienced under Stalin's regime. Fortunately, other 'centrifugal' forces are at work, destabilizing meaning by promoting diversity within society, whether as competing discourses or contrasting linguistic varieties. Here Bakhtin offered one of his most important concepts, that of 'heteroglossia,' where these competing centripetal and centrifugal forces enter into ongoing conflict, potentially sustaining internal diversity within a speech community, as separate but intermingling genres, registers, sociolects, discourses, and ideologies. In *Rabelais and his world* (1965), Bakhtin offered the telling image of the medieval carnival, where unofficial discourses and genres flourished, subversively contesting the centripetal forces of official hegemony.

Bilingual Education

C Baker, University of Wales, Bangor, North Wales, UK

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The term bilingual education has multiple meanings, with varying positive and negative associations, and a varied history. Take three cases. First, bilingual education is loosely used to refer to schools attended by bilingual children (e.g., Latinos and Latvians in U.S. schools, Greek and Gujarati children in U.K. schools). However, bilingualism is not fostered in such schools. Rather, the aim is to shift the child rapidly from the home, minority language to the dominant, majority language. Second, the term refers to children who are allowed to use their home language in the classroom for only a short period (e.g., one or two years) until they switch to the majority language (called transitional bilingual education). Third, bilingual education appears a more appropriate label for schools in which students learn through two languages in the classroom. For example, there are dual language schools in the United States that teach students through Spanish for one day and the next day through English. In Europe, there are elite bilingual programs (e.g., Luxembourg, Switzerland) in which children both learn, and learn through two or more prestigious languages (e.g., German, French, English).

Types of Bilingual Education

Given that bilingual education has multiple meanings, some clarity is possible by defining different types of bilingual education. Although Baker (2001) and

Garcia (1997), respectively, define 10 and 14 different types of bilingual education, a threefold categorization is helpful.

1. 'Null' forms of bilingual education bring together bilingual children but with the aim of monolingualism in the majority language. Submersion education is the term used in academic writing for such education, but not by school systems that tend to use the term mainstreaming. Submersion education implies that the child (on immediate entry to school) only experiences the majority language. The child is thrown into a language at the deep end and are expected to sink or swim in the majority language from the first day.
2. 'Weak' forms of bilingual education allow children to use their home language for a temporary period until they can switch totally to the majority language (Carrasquillo and Rodriguez, 2002). Weak forms of bilingual education include structured immersion, withdrawal classes, various forms of sheltered English, transitional bilingual education, and mainstreaming with foreign language teaching. Second language and foreign language teaching in schools occasionally produces competent bilinguals. Generally, such teaching does not result in age-appropriate proficiency in the second or foreign language, nor reaches a level of language that enables learning of curriculum content to occur via that language. Sometimes, a subset of language abilities is developed for instrumental or practical reasons (e.g., travel, trade, cultural awareness).

3. 'Strong' forms of bilingual education aim for each child, irrespective of ability, to achieve bilingualism, biliteracy, and cultural pluralism. Such outcomes are gained mainly through students learning content (e.g., mathematics, social studies) through both languages. Strong forms of bilingual education include U.S. dual language schools, Heritage Language programs, Canadian Immersion, and the European Schools movement. Three of these strong forms of bilingual education will be discussed here, so as to define education that has bilingualism as an educational outcome rather than bilingual children as an input.

Immersion Bilingual Education

Immersion education typically has students from majority language backgrounds (e.g., English homes in Canada; Swedish homes in Finland) and teaches them through another majority or a minority language (e.g., French in Canada). However, there are many variations: first, the age at which a child commences the experience. This may be at the kindergarten or infant stage (early immersion), at 9 to 10 years old (delayed or middle immersion), or at secondary level (late or late-start immersion). Second, the amount of time spent in immersion. Total immersion usually commences with 100% immersion in the second language, reducing after 2 or 3 years to 80% per week for the next 3 or 4 years, finishing junior schooling with approximately 50% immersion in the second language per week. Partial immersion provides close to 50% immersion in the second language throughout infant and junior schooling.

Children in early immersion are usually allowed to use their home language for a year or more for classroom communication. There is no compulsion to speak the second (school) language in the playground or when eating lunch. The child's home language is valued and not disparaged. Such children also start immersion education with relatively homogeneous language skills. This not only simplifies the teacher's task, it also means that students' self-esteem and classroom motivation are not threatened because of some students being linguistically more advanced.

Heritage Language Bilingual Education

Heritage language bilingual education occurs when language minority children use their native, ethnic, home, or heritage language in the school as a medium of instruction and the goal is competence in two languages. Examples include education through, or more often partly through, the medium of Navajo or Spanish in the United States (Francis and Reyhner, 2002), or Basque in Spain (Gardner, 2000),

or aboriginal languages in Australia (Caldwell and Berthold, 1995). In China, since 1979 minority language education has been provided for over 20 minority groups, partly as a way of improving ethnic minority relationships with central government (Blachford, 1997). In the Canadian provinces of Manitoba, British Columbia, Saskatchewan, and Alberta, there are heritage language bilingual education programs. The heritage language is the medium of instruction for about 50% of the day (e.g., Ukrainian, Italian, German, Hebrew, Yiddish, Mandarin Chinese, Arabic, and Polish). Heritage language programs in the United States (see Krashen *et al.*, 1998) and elsewhere vary in structure and content and overlap with the 90:10 model of dual language education (see later). Some of the likely features are described here.

Most of the children come from language minority homes but may be joined by a small number of majority language children whose parents desire bilingualism in their children. Such parents will often have the choice of sending their children to mainstream schools or to heritage language programs. In most cases, the majority language will also be used in the curriculum, ranging from second language lessons to a varying proportion (e.g., 10% to 50%) of the curriculum being taught in the majority language. There is a tendency to teach mathematical, technological, and scientific studies through the majority language, and to use the majority language progressively more across the grades.

Where a minority language is used for a majority of classroom time (e.g., 80% to almost 100%), the justification is that children easily transfer ideas, concepts, skills and knowledge into the majority language. Having taught a child multiplication in Mohawkian, this mathematical concept does not have to be retaught in English. The **justification** given for such programs is also that a minority language is easily lost, a majority language is easily gained. Children tend to be surrounded by the majority language, especially in the teenage years. Thus, bilingualism is achieved by an initial concentration on the minority language at school.

Dual Language Bilingual Education

U.S. dual language (or two-way) bilingual education typically occurs when there is an approximate balance in numbers between language minority and language majority students in the same classroom. Whereas a 50:50 **language balance** often was advised, the majority language can become dominant (e.g., because of its higher prestige value), putting the aim of bilingualism and biliteracy at risk.

Both languages are used for instruction and learning, revealing that the aim is to produce students

who are bilingual, biliterate, and bicultural or multicultural (Lindholm-Leary, 2001). Dual language schools use a non-English language for at least 50% of curriculum time for up to six grades. In each period of instruction, only one language is used, such that students learn a new language mostly via content. Genesee and Gándara (1999) suggest that such schools enhance intergroup communication and cultural awareness. They produce children who, in terms of intergroup relations, are likely to be more tolerant and sensitive. "Contact between members of different groups leads to increased liking and respect for members of the outgroup, including presumably reductions in stereotyping, prejudice, and discrimination" (Genesee and Gándara, 1999: 667).

Some teachers use both languages on different occasions with their students; others just use one language and may be paired and work together closely as a team. The school ethos also will be bilingual by classroom and corridor displays, curriculum resources, announcements, and extracurricular activity using both languages if possible.

A central idea in dual language bilingual schools is language separation and language boundaries. Language boundaries are established in terms of time, curriculum content and teaching. One frequent preference is for each language to be used on alternate days. Alternately, different lessons may use different languages with a regular change over to ensure both languages are used in all curricula areas. The division of time may be in half days, whole days, or alternate weeks. The essential element is the distribution of time to achieve bilingual and biliterate students. Often, a 50:50 balance in use of languages is attempted in early grades, although in some schools, the minority language is given more time (60% to 90% of the available time). In the later years of schooling, there is sometimes a preference for more emphasis on the majority language.

Bilingual Education and Politics

There is no deep understanding of bilingual education except through understanding the politics behind such education. There are varying philosophical and political origins to bilingual education that underpin different models of bilingual education. For example, bilingual education is best understood by reference to national variations (Cummins and Corson, 1998). The contrasting politics of Canada's two language solitudes and South Africa's management of social integration when retaining multilingualism, the ardor of language activists in the Basque Country and the more gentle revolution in Wales, the suppression of Breton in France, and the

historical repression of Native American Indian languages in the United States illustrate that the history and politics of a nation shapes its approach to languages and bilingual education.

The contemporary politics of bilingual education relates to the education of immigrants (e.g., in the United States, the United Kingdom), the preservation of nationalism (e.g., the fate of Breton in France), the devolution of power to regions (e.g., Wales, Catalonia), language revitalization (e.g., Native American Indians, the Maori in New Zealand), internationalism (e.g., the European Schools Movement, bilingual education in Japan), and the emancipatory education of deaf people (e.g., through bilingual education in a sign language and a majority language – see Baker and Jones, 1998). The varying politics of immigrant assimilation and political integration, economic protectionism and global trade, institutionalized racism and equality of opportunity, and recent debates about peace and terrorism can make bilingual education as much about politics as about education. Bilingual education also has become associated with political debates about dominance and control by elites, questions about social order, and the perceived potential subversiveness of language minorities (Garcia, 2002; Tollefson, 2002).

In Macedonia (Tankersley, 2001), China (Zhou, 2001), the United States (Wiese and Garcia, 2001), and the South Pacific (Lotherton, 1998), bilingual education also can be positively located within attempts to effect social, cultural, economic, or political change, particularly in strengthening the weak, empowering the powerless, and invigorating those most susceptible. This is illustrated by Tankersley (2001). Contextualized within the recent ethnic conflict in the Balkans, she examines a Macedonian/Albanian dual language program. The program demonstrated success in aiding community rebuilding after the war and the growth of cross-ethnic friendships. The research shows the potential for bilingual education program to develop students' respect for different languages and cultures, and help to resolve ethnic conflict. However, because the Macedonian language was connected with greater power and prestige, obtaining an equal balance of languages in the classroom was complex.

The importance of a historical perspective on bilingual education as politics is provided by Wiese and Garcia (2001) through an analysis of the U.S. Bilingual Education Act from 1968 to the present. The changing U.S. ideologies in minority language civil liberties, equality of educational opportunity, assimilation, and multiculturalism become translated into legislation and tested in litigation. Most recently, the No Child Left Behind Act of 2001 placed an

emphasis on accountability and testing. Whereas Title V authorizes programs for Native Indian, Native Hawaiian and Alaskan Native Education, Title III requires testing in English for most language minority students. All states are required to monitor the progress of some 3.68 million U.S. language minority students in meeting their English proficiency and academic objectives. The paradox is that the No Child Left Behind Act of 2001 followed the September 11 terrorist attacks. In the aftermath of the attacks, politicians, the press, and the public lamented the lack of language and cultural skills in U.S. intelligence and defense. It also seems possible that peace and harmony between religions and regions would be aided by producing bilinguals who appreciate the diversity that is possibly intrinsic in bilingualism and biculturalism.

Research and analysis of Proposition 227 in California has led to it being one of the most profiled examples of power and politics governing bilingual education (Stritikus, 2001; Crawford, 2004). In effect, Proposition 227 aimed at outlawing bilingual education in California. Proposition 227 was passed in a public ballot by a margin of 61% to 39%. Analysis of the voting and subsequent surveys found that Latinos were clearly against the proposition but, nevertheless, bilingual education became virtually illegal.

The importance of bilingual education for minority language literacy development and biliteracy has become a major recent theme (e.g., Martin-Jones and Jones, 2000; Hornberger, 2003). Using contexts of classroom, home, and community, such literacy research tends to be less concerned with teaching and learning methodology and more focused on, for example, the relationship between asymmetrical power relations and literacy practices that reproduce social inequalities and competing discourses about what counts as literacy. Current biliteracy research suggests that language policies and practices in education are struggles over power and authority, equity and marginalization, legitimacy and social order, symbolic domination and identities, social categorization, and social hierarchization. Any consideration about who should speak what language, how, when, and where is essentially about what counts as legitimate language and who has dominance and control. Hence, those in power who legitimate the current social order regulate access to linguistic norms and linguistic resources to preserve their power and position.

However cogent and coherent are the philosophical and pedagogic foundations for bilingualism, biliteracy, and biculturalism, however strong are the educational arguments for bilingual education,

and however strong are the arguments for the preservation of vanishing languages in the world, it is the politics of power, status, assimilation, and social order that can refute bilingual education so swiftly. However, bilingual education is typically a necessary, and sometimes an essential condition for the preservation of language species in the world. Where there is a shortfall in minority language reproduction in the family, then language production at school is essential in education to retain or increase the number and density of minority language speakers. From preschool bilingual education to adult language learning (e.g., in Ulpanim), bilingual education has a possible contemporary function not only to educate but also for minority language transmission.

Language Revitalization through Bilingual Education

Bilingual education is sometimes a component of national or regional language planning that varyingly attempts to assimilate indigenous and immigrant minorities, or integrate newcomers or minority groups (e.g., U.S., U.K.). On other occasions, bilingual education is a major plank in language revitalization and language reversal (e.g., among Native American Indians, the Sámi in Scandinavia, and the Maori in New Zealand).

The growing interest in endangered and dying languages has recently provided a further *raison d'être* to bilingual education. The predicted demise of many or most of the world's languages has created a momentum for language planning (Littlebear, 1999; Nettle and Romaine, 2000; Skutnabb-Kangas, 2000; Spolsky, 2004). For a minority language to survive, it has to produce new speakers, mostly via family language transmission and the education system (including adult language learning). Language planners tend to believe that bilingual education is an important means of language maintenance, language revitalization and reversing language shift, for example, among Native American Indians (Bia and McCarty, 2002; Francis and Reyhner, 2002; House, 2002), Ecuadorians (King, 2001), and the Basques (Gardner, 2000). Language acquisition planning via bilingual education becomes essential for language revival but insufficient by itself.

Nevertheless, bilingual education cannot gain its rational solely from language restoration or maintenance. It requires research to demonstrate underlying educational advantages (e.g., raising student achievement, increasing employment opportunities). There is sometimes over-optimism among language planners about what can be expected from and delivered by bilingual education in revitalizing a language.

Although bilingual education has an important role in language reproduction, and without bilingual education a minority language may not be able to survive except through intense religious usage, bilingual education cannot deliver language maintenance by itself.

The Advantages of 'Strong' Forms of Bilingual Education

Support for bilingual education tends to circle around eight interacting advantages of bilingual education that are claimed for students. There also are societal benefits that already have been alluded to in the above discussion of politics and bilingual education and will be briefly mentioned later. This section concentrates on the individual advantages.

First, bilingual education typically enables both languages to reach higher levels of competency. This potentially enables children to engage in wider communication across generations, regions, and cultural groups (Cummins, 2000). Second, bilingual education ideally develops a broader enculturation, a more sensitive view of different creeds and cultures. Bilingual education will usually deepen an engagement with the cultures associated with the languages, fostering a sympathetic understanding of differences, and, at its best, avoids the tight compartmentalization of racism and stereotyping. Third, strong forms of bilingual education frequently leads to biliteracy (see Hornberger, 2003). Accessing literacy practices in two or more languages adds more functions to a language (e.g., using in employment), widening the choice of literature for enjoyment, giving more opportunities for understanding different perspectives and viewpoints, and leading to a deeper understanding of history and heritage, of traditions and territory (Tse, 2001).

Fourth, research on dual language schools, Canadian immersion education, and heritage language education suggest that curriculum achievement is increased through content learning occurring via dual language curriculum strategies (Cummins, 2000; Tse, 2001). This is returned to later in this article. Fifth, plentiful research suggests that children with two well-developed languages share cognitive benefits (Bialystok, 2001). Such thinking advantages include being more creative because of their dual language systems (Baker, 2001), being more sensitive in communication as they may be interpersonally aware, for example, when needing to codeswitch, and tend to be more introspective of their languages (metalinguistic advantages – see Bialystok, 2001). Sixth, children's self-esteem may be raised in bilingual education for minority language students (Cummins, 2000). The opposite is when a child's home language is replaced by the majority language. Then, the child

itself, the parents and relatives, and not least the child's community may appear as inadequate and disparaged by the school system. When the home language is used in school, then children may feel themselves, their home, family, and community to be accepted, thus maintaining or raising their self-esteem.

Seventh, bilingual education may aid the establishment of a more secure identity at a local, regional, and national level. Sharing Welsh, Maori, or Native American Indian identity may be enhanced by the heritage language and culture being celebrated and honored in the classroom. Developing a Korean-American, Bengali-British, or Greek-Australian identity can be much aided by strong forms of bilingual education, and challenged or even negated by weak forms. Eighth, in some regions (e.g., Catalonia, Scandinavia) there are economic advantages for having experienced bilingual (or trilingual) education. Being bilingual can be important to secure employment in many public services and particularly when there is a customer interface requiring switching effortlessly between two or more languages. To secure a job as a teacher, to work in the mass media, to work in local government and increasingly in the civil service in countries such as Canada, Wales, and the Basque Country, bilingualism has become important. Thus, bilingual education is increasingly seen as delivering relatively more marketable employees than monolingual education (Dutcher, 1995; Tse, 2001).

To this list may be added the potential societal, ethnic group, or community benefits of bilingual education (May, 2001; Peyton *et al.*, 2001; Stroud, 2001; Tse, 2001) such as continuity of heritage, cultural vitality, empowered and informed citizenship, raising school and state achievement standards, social and economic inclusion, social relationships and networking, ethnic group self-determination, and distinctiveness. This is well illustrated by Feuerverger (2001) in an ethnography of a village (Neve Shalom/Wahat Al-Salam) in Israel, where Jews and Palestinians attempt to live together harmoniously and cooperatively, maintaining respect for the culture, identity, and languages of each group. This is partly attempted by two schools, an elementary school and the 'School for Peace,' which create bilingual Hebrew-Arabic bilinguals.

The Effectiveness of Bilingual Education

Research support for bilingual education is relatively robust (Baker, 2001) although there has been much political challenge to this in the United States (Crawford, 2004). Perhaps the strongest research support for bilingual education derives from

evaluations of immersion education, particularly from Canada since the 1960s (Johnstone, 2002). There is plentiful research from the United States since the 1960s (see Baker, 2001, for a review).

Evaluations of the effectiveness of dual language schools indicate relative success. One of the most wide-ranging evaluations of dual language schools is by Lindholm-Leary (2001). She analyzed teacher attributes, teacher talk, parental involvement and satisfaction, as well as student outcomes (using 4854 students) in different program types. These programs included Transitional Bilingual Education, English-Only, the 90:10 Dual Language Model, and the 50:50 Dual Language Model. The measured outcomes included Spanish and English language proficiency, academic achievement and attitudes of the students. Socioeconomic background and other student characteristics were taken into account in reporting results. Among a wealth of findings, Lindholm-Leary (2001) found that

- students who had 10% or 20% of their instruction in English scored as well on English proficiency as those in English-only programs and as well as those in 50:50 dual language (DL) programs;
- Spanish proficiency was higher in 90:10 than 50:50 (DL) programs. Students tended to develop higher levels of bilingual proficiency in the 90:10 than the 50:50 DL program;
- for Spanish-speaking students, no difference in English language proficiency was found between the 90:10 and 50:50 DL programs. However, DL students outperformed transitional bilingual education (TBE) students in English by the Grade 6;
- students in both the 90:10 and 50:50 DL programs were performing about 10 points higher in reading achievement than the Californian state average for English-speaking students educated in English-only programs;
- higher levels of bilingual proficiency were associated with higher levels of reading achievement;
- on Mathematics tests, DL students performed on average 10 points higher on Californian norms for English-speaking students educated only in English. There was a lack of difference in the scores of 90:10 and 50:50 DL students;
- DL students tended to reveal very positive attitudes toward their DL programs, teachers, classroom environment and the learning process.

Thomas and Collier's (2002) Final Report on their 1985 to 2001 database of 210,054 minority language students' academic achievement in eight different models of education indicates that: schooling in the home language has a much greater effect on achievement than socioeconomic status; late immigrants whose early education was in their

home language outperformed early immigrants schooled in English only; enrichment (heritage language) 90:10 programs and dual language programs (50:50) were the most academically successful for English L2 students and had the lowest dropout rates; the strongest predictor of L2 student achievement is the amount of formal L1 schooling with the more L1 schooling, the higher the L2 achievement; the highest quality ESL content programs reduce about half of the total achievement gap between those in enrichment or dual language programs and those without any bilingual support.

However, the reasons why research finds bilingual education linked with higher achievement are neither simple nor straightforward (August and Hakuta, 1997). There is likely to be a complex equation between such academic success and factors such as the support of the home (e.g., in encouraging literacy development), the devotion and dedication of teachers in school, children feeling their minority language is accepted and their self-esteem thus supported, and the positive relationship between bilingual education and cognitive development. Laosa (2000) reveals that school characteristics such as the quality and ratio of teachers per student, the teacher's credentials, and fragmentation of instruction are potentially influential in student achievement. That is, particular models of bilingual education interact with a host of student, teacher, curriculum, and environmental variables in complex ways to influence student outcomes. It cannot be assumed that bilingual education, *per se*, results in higher attainment across the curriculum. There are many interacting variables that will underlie such success with no simple recipes for guaranteed success.

The English Language and Bilingual Education

The paradox of English in bilingual education is illustrated by the research of Valdés (2001). English language learning policies enacted in schools can deny access to the language and knowledge that would empower U.S. immigrant children. Valdés (2001) shows that, separately and cumulatively, there are complex interacting classroom factors that frequently work against a student's second language development, achievement, employment, citizen rights and opportunities, and self-esteem. Such factors include a lack of regular, purposeful, and developing interactions with native speakers, impoverished second language interactions with teachers on a staff-student ratio of over 1:30, passive learning and 'tight discipline' strategies, mixed language competence classes working to a low common denominator, subject matter kept simplistic as the second language

is insufficiently developed, and teachers' concerns with 'flawed language' forms rather than communication: "Placing blame is not simple. Structures of dominance in society interact with educational structures and educational ideologies as well as with teachers' expectations and with students' perspectives about options and opportunities" (Valdés, 2001: 4).

The 'English language dominance' dangers for bilingual education also are found in access to Information Communications Technology (ICT) for language minority students. ICT is often dominated by the English language. This relates to current debates about the place of the English language in bilingual education in the context of the internationalization of English and its growing worldwide prominence as a second language rather than a mother tongue (Graddol and Meinhof, 1999). In contrast, there are potential opportunities to support the future of minority languages in education through ICT such as e-books, machine translation, voice recognition, WebTV, international e-mailing, and text messaging (Skourtou, 2002).

The Limitations of Bilingual Education

Although bilingual education has an increasing number of international supporters, it is not without some political critics, especially in the United States – see Cummins (2000) for a review. This has been considered earlier. There also are limitations to the pedagogical view of bilingual education. Bilingual education is no absolute guarantee of effective schooling. It is ingenuous to imagine that employing two or more languages in the school curriculum automatically leads to a raising of achievement, more effective schooling, or a more child-centered education. In reality, the languages of the school are but part of an extensive matrix of variables that interact in complex ways to make schooling more or less effective. Among bilingual schools in every country, there is often a mixture of the outstanding and the ordinary, those in an upward spiral of enhancing their quality, and those that depend on past glories rather than current successes. The school effectiveness research movement has located many of the important factors that make such schools more or less effective (August and Hakuta, 1997). Bilingual education is only one ingredient among many.

Another limitation of the pedagogical perspective on bilingual education is the nature and use of language learned at school. Canadian research suggests that the language register of formal (e.g., immersion) education does not necessarily prepare children for language use outside the school (Cummins, 2000). The language of the curriculum is increasingly complex and specialized. The vernacular of the peer group and the lingo of the

street is different. Canadian children from English-speaking homes who have been to immersion schools and learnt through the medium of French and English sometimes report difficulty in communicating appropriately with French speakers in local communities. Local French speakers can find such students' French too formal, awkward, or even inappropriate.

A further concern about bilingual education is that language learning may stop at the school gates. The minority language may be effectively transmitted and competently learned in the classroom. Once outside the school gates, children may switch into the majority language for reasons of status, acceptance by peers, and inclusiveness in peer relations (that is, the majority language is often the 'common denominator' language). Thus, the danger of bilingual education in a minority language is that the language becomes a language of school but not of play; a language of the content delivery of the curriculum but not of peer culture. Extending a minority language learnt at school to use in the community over the teenage and adulthood years is something that is difficult to engineer, difficult to plan, but nevertheless vital if that language is to live outside the school gates.

Bilingualism

Li Wei, Birkbeck College, University of London, London, UK

What Is Bilingualism?

Bilingualism is a product of extensive language contact (i.e., contacts between people who speak different languages). There are many reasons for speakers of different languages to get into contact with one another. Some do so out of their own choosing, whereas others are forced by circumstances. Among the frequently cited factors that contribute to language contact are education, modern technology, economy, religion and culture, political or military acts, and natural disasters. One does not have to move to a different place to be in contact with people speaking a different language. There are plenty of opportunities for language contact in the same country, the same community, the same neighborhood, or even the same family.

However, although language contact is a necessary condition for bilingualism at the societal level, it does not automatically lead to bilingualism at the individual level. For example, Belgium, Canada, Finland, India, Luxembourg, Paraguay, and Singapore, to name but a few countries, are bi- or multilingual, but the degree or extent of bilingualism among the residents of these countries varies significantly. There are large numbers of bilingual or multilingual individuals in Luxembourg, Paraguay, and Singapore, but considerably fewer in the other officially bi- or multilingual countries. Mackey (1962) claims that there are actually fewer bilingual people in bilingual countries than there are in the so-called 'unilingual' ones, because the main concerns of bi- or multilingual states are often the maintenance and use of two or more languages in the same nation, rather than the promotion of bilingualism among their citizens. It is therefore important to distinguish bilingualism as a social or societal phenomenon from bilingualism as an individual phenomenon.

Who Is Bilingual?

People who are brought up in a society in which monolingualism and uniculturalism are promoted as the normal way of life often think that bilingualism is only for a few, 'special' people. In fact, one in three of the world's population routinely uses two or more languages for work, family life, and leisure. There are even more people who make irregular use of languages other than their native one; for example,

many people have learned foreign languages at school and only occasionally use them for specific purposes. If we count these people as bilinguals, then monolingual speakers would be a tiny minority in the world today.

Yet the question of who is and who is not a bilingual is more difficult to answer than it first appears. Baker and Prys Jones (1998: 2) suggest that in defining a bilingual person, we may wish to consider the following questions:

- Should bilingualism be measured by how fluent people are in two languages?
- Should bilinguals be only those people who have equal competence in both languages?
- Is language proficiency the only criterion for assessing bilingualism, or should the use of two languages also be considered?
- Most people would define a bilingual as a person who can speak two languages. What about a person who can understand a second language perfectly but cannot speak it? What about a person who can speak a language but is not literate in it? What about an individual who cannot speak or understand speech in a second language but can read and write it? Should these categories of people be considered bilingual?
- Should self-perception and self-categorization be considered in defining who is bilingual?
- Are there different degrees of bilingualism that can vary over time and with circumstances? For instance, a person may learn a minority language as a child at home and then later acquire another, majority language in the community or at school. Over time, the second language may become the stronger or dominant language. If that person moves away from the neighborhood or area in which the minority language is spoken or loses contact with those who speak it, he or she may lose fluency in the minority language. Should bilingualism therefore be a relative term?

The word 'bilingual' primarily describes someone with the possession of two languages. It can, however, also be taken to include the many people in the world who have varying degrees of proficiency in and interchangeably use three, four or even more languages. In many countries of Africa and Asia, several languages coexist and large sections of the population speak three or more languages. Individual multilingualism in these countries is a fact of life. Many people speak one or more local or ethnic languages, as well as another indigenous language which has become the medium of communication between different ethnic

groups or speech communities. Such individuals may also speak a foreign language – such as English, French or Spanish – which has been introduced into the community during the process of colonization. This latter language is often the language of education, bureaucracy and privilege.

Multilingualism can also be the possession of individuals who do not live within a multilingual country or speech community. Families can be trilingual when the husband and wife each speak a different language as well as the common language of the place of residence. People with sufficient social and educational advantages can learn a second, third, or fourth language at school or university; at work; or in their leisure time. In many continental European countries, children learn two languages at school – such as English, German, or French – as well as being fluent in their home language – such as Danish, Dutch, or Luxembourgish.

It is important to recognize that a multilingual speaker uses different languages for different purposes and does not typically possess the same level or type of proficiency in each language. In Morocco, for instance, a native speaker of Berber may also be fluent in colloquial Moroccan Arabic but not literate in either of these languages. This Berber speaker will be educated in Modern Standard Arabic and use that language for writing and formal purposes. Classical Arabic is the language of the mosque, used for prayers and reading the Qur'an. Many Moroccans also have some knowledge of French, the former colonial language.

Theoretical Issues in Bilingualism Research

Chomsky (1986) defined three basic questions for modern linguistics:

- i. What constitutes knowledge of language?
- ii. How is knowledge of language acquired?
- iii. How is knowledge of language put to use?

For bilingualism research, these questions can be rephrased to take in knowledge of more than one language (see also Cook, 1993):

- i. What is the nature of language, or grammar, in the bilingual person's mind, and how do two systems of language knowledge coexist and interact?
- ii. How is more than one grammatical system acquired, either simultaneously or sequentially? In what aspects does bilingual language acquisition differ from unilingual language acquisition?

- iii. How is the knowledge of two or more languages used by the same speaker in bilingual speech production?

Taking the acquisition question first, earlier observers of bilingual children concentrated on documenting the stages of their language development. Volterra and Taeschner (1978), for example, proposed a three-stage model of early bilingual development. According to this model, the child initially possesses one lexical system composed of lexical items from both languages. In stage two, the child distinguishes two separate lexical codes but has one syntactic system at his or her disposal. Only when stage three is reached do the two linguistic codes become entirely separate. Volterra and Taeschner's model gave rise to what is now known as the 'unitary language system hypothesis.' In its strongest version, the hypothesis supposes that the bilingual child has one single language system that they use for processing both of their languages in the repertoire.

In the 1980s, the unitary language system hypothesis came under intense scrutiny; for instance, by Meisel (1989) and Genesee (1989). They argue that there is no conclusive evidence to support the existence of an initial undifferentiated language system, and they also point out certain methodological inconsistencies in the three-stage model. The phenomenon of language mixing, for instance, can be interpreted as a sign of two developing systems existing side by side, rather than as evidence of one fused system. Meisel's and Genesee's studies led to an alternative hypothesis, known as the 'separate development hypothesis' or 'independent development hypothesis.' More recently, researchers have investigated the possibility that different aspects of language (e.g., phonology, vocabulary, syntax, pragmatics) of the bilingual child's language systems may develop at different rates (e.g., Li and Zhu, 2001). Care needs to be taken in interpreting research evidence using children at different developmental stages.

Although the 'one-versus-two-systems' debate (i.e., whether bilingual children have an initially differentiated or undifferentiated linguistic system) continues to attract new empirical studies, a more interesting question has emerged regarding the nature of bilingual development. More specifically, is bilingual acquisition the same as monolingual acquisition? Theoretically, separate development is possible without there being any similarity with monolingual acquisition. Most researchers argue that bilingual children's language development is, by and large, the same as that of monolingual children. In very general terms, both bilingual and monolingual children go through an initial babbling stage, followed by the

one-word stage, the two-word stage, the multiword stage, and the multclause stage. At the morpho-syntactic level, a number of studies have reported similarities rather than differences between bilingual and monolingual acquisition. Garcia (1983), for example, compared the use of English morpheme categories by English monolingual children and bilingual children acquiring English and Spanish simultaneously and found no systematic difference at all. Pfaff and Savas (1988) found that their 4-year-old Turkish/German subject made the same errors in Turkish case marking as reported in the literature on monolingual Turkish children. Muller's (1990) study of two French/German children indicates that their use of subject-verb agreement and finite verb placement in both languages is virtually identical to that of comparable monolingual children. De Houwer (1990) found that her Dutch/English bilingual subject, Kate, used exactly the same word orders in Dutch as monolingual Dutch-speaking children, both in terms of types and in proportional use. Furthermore, De Houwer found in Kate parallels to monolingual children for both Dutch and English in a range of structures, such as nonfinite verb placement, preposed elements in affirmative sentences, clause types, sentence types, conjunctions, and question inversion.

Nevertheless, one needs to be careful in the kinds of conclusions one draws from such evidence. Similarities between bilingual and monolingual acquisition do not mean that the two languages a bilingual child is acquiring develop in the same way or at the same speed, or that the two languages a bilingual child is acquiring do not influence and interact with each other. Paradis and Genesee (1996), for example, found that although the 2-3-year-old French-English bilingual children they studied displayed patterns that characterize the performance of monolingual children acquiring these languages separately, and they acquired these patterns within the same age range as monolingual children, they used finite verb forms earlier in French than in English; used subject pronouns in French exclusively with finite verbs, but subject pronouns in English with both finite and non-finite verbs, in accordance with the status of subject pronouns in French as clitics (or agreement markers) but full NPs in English; and placed verbal negatives after lexical verbs in French (e.g., 'n'aime pas') but before lexical verbs in English ('do not like'). Further evidence of cross-linguistic influence has been reported by Dopke (1992), for example, in her study of German-English bilingual children in Australia. These children tended to overgeneralize the VO word order of English to German, which instantiates both VO and OV word orders, depending on the clausal structure of the utterance. Dopke suggests

that children learning English and German simultaneously are prone to overgeneralize SVO word order in their German because the VO order is reinforced on the surface of both the German and the English input they hear.

Most of the studies that have examined cross-linguistic influences in bilingual acquisition focus on morphosyntactic features. One area that has hitherto been underexplored is the interface between phonetics and phonology in bilingual acquisition. Although most people seem to believe that the onset of speech in the case of bilingual children is more or less the same as for monolingual children, there are indications that bilingual children seem to develop differently from monolingual children in the following three aspects: the overall rate of occurrence of developmental speech errors, the types of speech errors and the quality of sounds (Zhu and Dodd, 2005). For example, studies on Cantonese/English (Holm and Dodd), Putonghua/Cantonese (So and Leung), Welsh/English (Ball *et al.*), Spanish/English (Yavas and Goldstein), and Punjabi/English (Stow and Pert) (also in Zhu and Dodd, 2006) bilingual children seem to indicate that bilingual children tend to make not only more speech errors but also different types of speech errors compared with monolingual children of the same age. These speech errors would be considered atypical if they had occurred in the speech of monolingual children. Moreover, although bilingual children seem to be able to acquire monolingual-like competence at the phonemic level, there are qualitative differences at the phonetic level in terms of production. For example, using instrumental analysis, Khattab (also in Zhu and Dodd, 2006) finds that although Arabic-English bilingual children have similar patterns of production and use of VOT, /l/, and /r/ in some respects to those of monolinguals from each language, they also show differences that are intricately related to age, input, and language context. These studies and others are reported in Zhu and Dodd (2005).

There is one area in which bilingual children clearly differ from monolingual children; namely, code-mixing. Studies show that bilingual children mix elements from both languages in the same utterance as soon as they can produce two-word utterances. Researchers generally agree that bilingual children's mixing is highly structured and grammatically constrained, although there is no consensus on the nature of the specific constraints that organize their mixing. Vihman (1985), who studied her own son Raivo, who acquired English and Estonian simultaneously, argued, for example, that the language mixing by bilingual children is qualitatively different from that of more mature bilinguals. She invoked as evidence for this claim the fact that young bilingual children

indicate a propensity to mix function words over contentives (e.g., nouns, verbs, adjectives) – a type of mixing that is rare in older bilingual mixing. However, Lanza's (1997) study, although finding similar patterns in the mixing produced by her two Norwegian–English bilingual subjects, argued that children's mixing is qualitatively the same as that of adults; their relatively greater degree of mixing of function words is evidence of what Lanza called 'dominance' of one language over another rather than of a substantial difference from bilingual adults' mixing. Both Vihman's and Lanza's, as well as other studies of children's mixing, show that bilingual children mix their languages in accordance with constraints that operate on adult mixing. The operation of constraints based on surface features of grammar, such as word order, is evident from the two-word/two-morpheme stage onward, and the operation of constraints based on abstract notions of grammatical knowledge is most evident in bilingual children once they demonstrate such knowledge overtly (e.g., verb tense and agreement markings), usually around two years and 6 months of age and older. As Genesee (2002) points out, these findings indicate that in addition to the linguistic competence needed to formulate correct monolingual strings, bilingual children have the added capacity to coordinate their two languages in accordance with the grammatical constraints of both languages during mixing. Although these studies provide further evidence for the separate development, or two-systems, argument, they also indicate that there are both quantitative and qualitative differences between bilingual acquisition and monolingual acquisition.

Another area of interest in acquisitional studies of bilingual children is the role of input and social context in the rate and order of language acquisition. Earlier assumptions were that the bilingual child would have half, or less, of the normal input in each of their two languages, compared with the monolingual child. More careful examinations of bilingual children show considerable variations in the quantity and quality of input, interactional styles of the parents, and environmental policies and attitudes toward bilingualism. On the basis of Harding and Riley's work (1986), Romaine (1995) distinguished six types of early-childhood bilingualism according to the native language of the parents, the language of the community at large, and the parents' strategy in speaking to the child.

Type 1: One person, one language.

- Parents: The parents have different native languages, with each having some degree of competence in the other's language.

- Community: The language of one of the parents is the dominant language of the community.
- Strategy: The parents each speak their own language to the child from birth.

Type 2: Nondominant Home Language/One Language, One Environment

- Parents: The parents have different native languages.
- Community: The language of one of the parents is the dominant language of the community.
- Strategy: Both parents speak the nondominant language to the child, who is fully exposed to the dominant language only when outside the home, and in particular in nursery school.

Type 3: Nondominant Home Language without Community Support

- Parents: The parents share the same native languages.
- Community: The dominant language is not that of the parents.
- Strategy: The parents speak their own language to the child.

Type 4: Double Nondominant Home Language without Community Support

- Parents: The parents have different native languages.
- Community: The dominant language is different from either of the parents.
- Strategy: The parents each speak their own language to the child from birth.

Type 5: Nonnative Parents

- Parents: The parents share the same native language.
- Community: The dominant language is the same as that of the parents.
- Strategy: One of the parents always addresses the child in a language that is not his or her native language.

Type 6: Mixed Languages

- Parents: The parents are bilingual.
- Community: Sectors of community may also be bilingual.
- Strategy: Parents code-switch and mix languages.

The three headings Romaine used to classify the six types of childhood bilingualism – the languages of the parents, the sociolinguistic situation of the community, and the discourse strategies of the parents and other immediate carers – are critical factors not only in the process of bilingual acquisition but also in

the final product of that process (i.e., the type of bilingual speaker it produces). Arguably, the six types of bilingual children would grow up as different types of bilinguals with different mental representations of the languages and different patterns of language behavior.

Research on the cognitive organization and representation of bilingual knowledge is inspired and influenced by the work of Weinreich. Focussing on the relationship between the linguistic sign (or signifier) and the semantic content (signified), Weinreich (1953) distinguished three types of bilinguals. In type A, the individual combines a signifier from each language with a separate unit of the signified. Weinreich called them 'coordinative' (later often called 'coordinate') bilinguals. In type B, the individual identifies two signifiers but regards them as a single compound, or composite, unit of signified; hence 'compound' bilinguals. Type C refers to people who learn a new language with the help of a previously acquired one. They are called 'subordinative' (or 'subordinate') bilinguals. Weinreich's examples were from English and Russian:

- (A) 'book' 'kniga'
 | |
 /buk/ /kn'iga/
- (B) 'book' = 'kn'iga'
 /buk/ /kn'iga/
- (C) 'book'
 |
 /buk/
 |
 /kn'iga/

Weinreich's distinctions are often misinterpreted in the literature as referring to differences in the degree of proficiency in the languages, but in fact the relationship between language proficiency and cognitive organization of the bilingual individual, as conceptualized in Weinreich's model, is far from clear. Some 'subordinate' bilinguals demonstrate a very high level of proficiency in processing both languages, as evidenced in grammaticality and fluency of speech, and some 'coordinative' bilinguals show difficulties in processing two languages simultaneously (i.e., in code-switching or in 'foreign' word identification tasks). It must also be stressed that Weinreich's distinctions among bilingual individuals are distributed along a continuum from a subordinate or compound end to a coordinate end and can at the same time be more subordinate or compound for certain concepts

and more coordinate for others, depending on, among other things, the age and context of acquisition.

Weinreich's work influenced much of the psycholinguistic modelling of the bilingual lexicon. Potter *et al.* (1984) presented a reformulation of the manner in which bilingual lexical knowledge could be represented in the mind in terms of two competing models: the Concept Mediation Model and the Word Association model. In the Concept Mediation Model, words of both L1 and L2 are linked to amodal conceptual representations. In the Lexical Association Model, in contrast, words in a second language are understood through L1 lexical representations. As can be seen in **Figure 1**, the models are structurally equivalent to Weinreich's distinction between coordinative and subordinative bilingualism. At the same time, several researchers (e.g., Kolers and Gonzalez [1980] and Hummel [1986]) presented evidence for the so-called dual-store model, as represented in **Figure 2**. This latter model has also generated considerable research on the existence of the putative 'bilingual language switch' postulated to account for the bilingual's ability to switch between languages on the basis of environmental demands (e.g., MacNamara, 1967; MacNamara and Kushnir, 1971).

Subsequent studies found conflicting evidence in favor of different models. Some of the conflicting evidence could be explained by the fact that different types of bilingual speakers were used in the experiments in terms of proficiency level, age, and context of acquisition. It is possible that lexical mediation is associated with low levels of proficiency, and concept mediation with higher levels, especially for those who have become bilingual in later childhood or adulthood. Some researchers called for a developmental dimension in the modelling of bilingual knowledge. Kroll and Stewart (1994), for example, proposed the Revised Hierarchical Model, which represents concept mediation and word association not as different models but as alternative routes within the same model (see **Figure 3**).

An important distinctive feature of being bilingual is being able to make appropriate language choices. Bilingual speakers choose to use their different

Figure 1 Lexical association model.

Figure 2 Dual-store model.

Figure 3 Revised hierarchical model.

languages depending on a variety of factors, including the type of person addressed (e.g., members of the family, schoolmates, colleagues, superiors, friends, shopkeepers, officials, transport personnel, neighbors), the subject matter of the conversation (e.g., family concerns, schoolwork, politics, entertainment), location or social setting (e.g., at home, in the street, in church, in the office, having lunch, attending a lecture, negotiating business deals), and relationship with the addressee (e.g., kin, neighbors, colleagues, superior/inferior, strangers). However, even more complex are the many cases in which a bilingual talks to another bilingual with the same linguistic background and changes from one language to another in the course of conversation. This is what is known as code-switching. **Figure 4** illustrates a decision-making process of the bilingual speaker in language choice and code-switching.

There is a widespread impression that bilingual speakers code-switch because they cannot express themselves adequately in one language. This may be true to some extent when a bilingual is momentarily lost for words in one of his or her languages. However, code-switching is an extremely common practice among bilinguals and takes many forms. A long narrative may be divided into different parts expressed in different languages, sentences may begin in one language and finish in another, and words and phrases from different languages may succeed each other. Linguists have devoted much attention to the study of code-switching. It has been demonstrated that code-switching involves skilled manipulation of overlapping sections of two or more grammars and

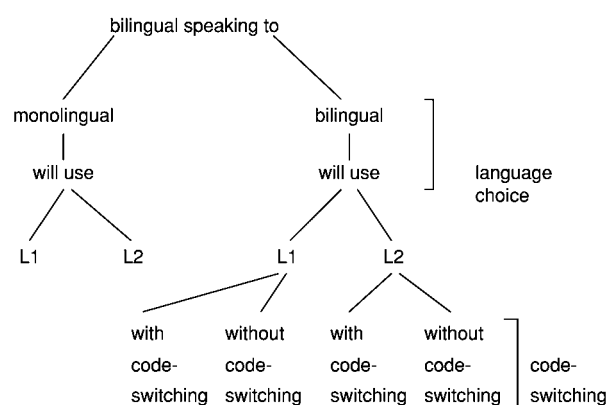

Figure 4 Adapted from Grosjean, 1982: 129.

that there is virtually no instance of ungrammatical combination of two languages in code-switching, regardless of the bilingual ability of the speaker. Some suggest that code-switching is itself a discrete mode of speaking, emanating from a single code-switching grammar.

One important aspect of the code-switching grammar is that the two languages involved do not play the same role in sentence making. Typically, one language sets the grammatical framework, with the other providing certain items to fit into the framework. Code-switching therefore is not a simple combination of two sets of grammatical rules but grammatical integration of one language in another. Bilingual speakers of different proficiency levels in their two languages or speaking two typologically different languages can engage in code-switching and, indeed, vary it according to their needs. The possible existence of a code-switching grammar calls into question the traditional view of the bilingual as two monolinguals in one person (for further discussions, see Grosjean, 1985). One consequence of the 'two-in-one' perspective is that bilingual speakers are often compared to monolinguals in terms of their language proficiency.

For example, some researchers have suggested that bilingual children have smaller vocabularies and less-developed grammars than their monolingual peers, while their ability to exploit the similarities and differences in two sets of grammatical rules to accomplish rule-governed code-switching was not considered relevant. In some experimental psycholinguistic studies, tests are given without taking into account that bilingual speakers may have learned their two languages under different conditions for different purposes and that they only use them in different situations with different people. It is important to emphasize that bilingual speakers have a unique

linguistic and psychological profile; their two languages are constantly in different states of activation, and they are able to call on their linguistic knowledge and resources according to the context and adapt their behavior to the task at hand.

Bilingualism as a Sociopolitical Issue

Language choice is not a purely linguistic issue. In many countries of the world, much of the social identification of individuals, as well as of groups, is accomplished through language choice. By choosing one or another of the two or more languages in one's linguistic repertoire, a speaker reveals and defines his or her social relationships with other people. At a societal level, whole groups of people, and in fact, entire nations, can be identified by the language or languages they use. Language, together with culture, religion, and history, is a major component of national identity.

Multilingual countries are often thought to have certain problems that monolingual states do not. On the practical level, difficulties in communication within a country can act as an impediment to commerce and industry. More seriously, however, multilingualism is a problem for government. The process of governing requires communication both within the governing institutions and between the government and the people. This means that a language, or languages, must be selected as the language for use in governing. However, the selection of the 'official language' is not always easy, as it is not simply a pragmatic issue. For example, on pragmatic grounds, the best immediate choice for the language of government in a newly independent colony might be the old colonial language, as the colonial governing institutions and records are already in place in that language, and those nationals with the most government experience already know it. The old colonial language will not, however, be a good choice on nationalist grounds. For a people that has just acquired its own geographical territory, the language of the state that had denied it territorial control would not be a desirable candidate for a national symbol. Ireland has adopted a strategy in which both the national language, Irish, and the language of the deposed power, English, are declared as official; the colonial language is used for immediate, practical purposes, and the national language is promoted and developed. However, in many other multilingual countries that do not have a colonial past, such as China, deciding which language should be selected as the national language can sometimes lead to internal, ethnic conflicts.

Similarly, selecting a language for education in a multilingual country is often problematic. In some

respects, the best strategy for language in education is to use the various ethnic languages. After all, these are the languages the children already speak, and school instruction can begin immediately without waiting until the children learn the official language. Some would argue, however, that this strategy could be damaging for nation-building efforts and disadvantage children by limiting their access to the wider world. It should be pointed out that there is no scientific evidence to show that multilingual countries are particularly disadvantaged, in socioeconomic terms, compared to monolingual ones. In fact, all the research that was carried out in the 1960s and 1970s on the relationship between the linguistic diversity and economic well-being of a nation came to the conclusion that a country can have any degree of language uniformity or fragmentation and still be underdeveloped, and a country whose entire population speaks the same language can be anywhere from very rich to very poor. It might be true, however, that linguistic uniformity and economic development reinforce each other; in other words, economic well-being promotes the reduction of linguistic diversity. It would be lopsided logic, though, to view multilingualism as the cause of the socioeconomic problems of a nation.

Multilingualism is an important resource at both the societal and personal levels. For a linguistically diverse country to maintain ethnic group languages alongside the national or official languages can prove an effective way to motivate individuals while unifying the nation. In addition, a multiethnic society is arguably a richer, more exciting, and more stimulating place to live in than a community with only one dominant ethnic group. For the multilingual speaker, the availability of various languages in the community repertoire serves as a useful interactional resource. Typically, multilingual societies tend to assign different roles to different languages; one language may be used in informal contexts with family and friends, while another for the more formal situations of work, education, and government. Imagine two friends who are both bilingual in the same 'home' and 'official' languages. Suppose that one of them also works for the local government and that her friend has some official business with her. Suppose further that the government employee has two pieces of advice to give to her friend: one based on her official status as a government representative, and one based on their mutual friendship. If the official advice is given in the 'government' language and the friendly advice in the 'home' language, there is little chance that there would be any misunderstanding about which advice was which. The friend would not take the advice given in the 'home' language as official.

There is a frequent debate in countries in which various languages coexist concerning which languages are a resource. The favored languages tend to be those that are both international and particularly valuable in international trade. A lower place is given in the status ranking to minority languages, which are small, regional, and of less perceived value in the international marketplace. For example, French has traditionally been the number one modern language in the British school curriculum, followed by German and Spanish, and then a choice between Italian, Modern Greek, and Portuguese. One may notice that all of these are European languages. Despite large numbers of mother-tongue Bengali, Cantonese, Gujarati, Hakka, Hindi, Punjabi, Turkish, and Urdu speakers in England, these languages occupy a very low position in the school curriculum. In the British National Curriculum, the languages Arabic, Bengali, Chinese (Cantonese or Mandarin), Gujarati, Modern Hebrew, Hindi, Japanese, Punjabi, Russian, Turkish, and Urdu are initially only allowed in secondary schools (for 11–18 year olds) if a major European language such as French is taught first (Milroy and Milroy, 1985).

Clearly, multilingualism as a national and personal resource requires careful planning, as would any other kind of resource. However, language planning has something that other kinds of economic planning do not usually have: language as its own unique cultural symbolic value. As has been discussed earlier, language is a major component of the identity of a nation and an individual. Often, strong emotions are evoked when talking about a certain language. Language planning is not simply a matter of standardizing or modernizing a corpus of linguistic materials, nor is it a reassignment of functions and status. It is also about power and influence. The dominance of some languages and the dominated status of other languages are partly understandable if we examine who hold positions of power and influence, who belong to elite groups that are in control of decision-making, and who are in subordinate groups, on whom decisions are implemented. It is more often than not the case that a given arrangement of languages benefits only those who have influence and privileges.

For the multilingual speaker, language choice is not only an effective means of communication but also an act of identity (Le Page and Tabouret-Keller, 1985). Every time we say something in one language when we might just as easily have said it in another, we are reconnecting with people, situations, and power configurations from our history of past interactions and imprinting on that history our attitudes toward

the people and languages concerned. Through language choice, we maintain and change ethnic group boundaries and personal relationships and construct and define ‘self’ and ‘other’ within a broader political economy and historical context.

Changes in Attitudes Toward Bilingualism

From the early nineteenth century to about the 1960s, there was a widespread belief that bilingualism has a detrimental effect on a human beings’ intellectual and spiritual growth. Stories of children who persisted in speaking two languages in school having had their mouths washed with soap and water or being beaten with a cane were not uncommon. The following is a quote from a professor at Cambridge University that illustrates the dominant belief of the time, even among academics and intellectuals:

If it were possible for a child to live in two languages at once equally well, so much the worse. His intellectual and spiritual growth would not thereby be doubled, but halved. Unity of mind and character would have great difficulty in asserting itself in such circumstances. (Laurie, 1890: 15)

Professor Laurie’s view represented a commonly held belief throughout the twentieth century that bilingualism disadvantages rather than advantages one’s intellectual development. Early research on bilingualism and cognition tended to confirm this negative viewpoint, finding that monolinguals were superior to bilinguals on intelligence tests. One of the most widely cited studies was done by Saer (1923) who studied 1400 Welsh–English bilingual children between the ages of 7 and 14 years in five rural and two urban areas of Wales. A 10-point difference in IQ was found between the bilinguals and the monolingual English speakers from rural backgrounds. From this, Saer concluded that bilinguals were mentally confused and at a disadvantage in intelligence compared with monolinguals. It was further suggested, with a follow-up study of university students, that “the difference in mental ability as revealed by intelligence tests is of a permanent nature since it persists in students throughout their university career” (Saer, 1923: 53).

Controversies regarding the early versions of IQ tests and the definition and measurement of intelligence aside, there were a number of problems with Saer’s study and its conclusions. First, it appeared to be only in the rural areas that the correlation between bilingualism and lower IQ held. In urban areas, monolinguals and bilinguals were

virtually the same; in fact, the average IQ for urban Welsh–English bilingual children in Saer’s study was 100, whereas for monolingual, English-speaking children it was 99. The urban bilingual children had more contact with English both before beginning school and outside school hours than did the rural bilinguals. Thus, the depressed scores of the rural population were probably more a reflection of lack of opportunity and contexts to use English and were not necessarily indicative of any sociopsychological problems.

More important, however, is the issue of statistical inference in this and other studies of a similar type. Correlations do not allow us to infer cause-and-effect relationships, particularly when other variables – such as rural versus urban differences – may be mediating factors. Another major factor is the language in which such tests were administered, particularly tests of verbal intelligence. Many such studies measured bilinguals only in the second or nondominant language.

At around the same time that Saer conducted studies on bilinguals’ intelligence, some well-known linguists expressed their doubts about bilingual speakers’ linguistic competence. The following is Bloomfield’s characterization of a Menomini Indian man in the United States, whom he believed to have ‘deficient’ knowledge of Menomini and English:

White Thunder, a man around 40, speaks less English than Menomini, and that is a strong indictment, for his Menomini is atrocious. His vocabulary is small, his inflections are often barbarous, he constructs sentences of a few threadbare models. He may be said to speak no language tolerably. (Bloomfield, 1927: 395)

This is one of the early statements of a view that became fashionable in educational circles; namely, that it was possible for bilinguals not to acquire full competence in any of the languages they spoke. Such an individual was said to be ‘semilingual.’ These people were believed to have linguistic deficits in six areas of language (see Hansegard, 1975; Skutnabb-Kangas, 1981):

1. Size of vocabulary
2. Correctness of language
3. Unconscious processing of language
4. Language creation
5. Mastery of the functions of language
6. Meanings and imagery.

It is significant that the term ‘semilingualism’ emerged in connection with the study of language skills of people belonging to ethnic minority groups. Research that provided evidence in support of the notion of ‘semilingualism’ was conducted in

Scandinavia and North America and was concerned with accounting for the educational outcomes of submersion programs in which minority children were taught through the medium of the majority language. However, these studies, similar to the ones conducted by Saer, had serious methodological flaws, and the conclusions reached by the researchers were misguided.

First, the educational tests used to measure language proficiencies and to differentiate between people were insensitive to the qualitative aspects of languages and to the great range of language competences. Language may be specific to a context; a person may be competent in some contexts but not in others. Second, bilingual children are still in the process of developing their languages. It is unfair to compare them to some idealized adults. Their language skills change over time. Third, the comparison with monolinguals is also unfair. It is important to distinguish whether bilinguals are ‘naturally’ qualitatively and quantitatively different from monolinguals in their use of the two languages (i.e., as a function of being bilingual). Fourth, if languages are relatively underdeveloped, the origins may not be in bilingualism per se but in the economic, political, and social conditions that evoke underdevelopment.

The disparaging and belittling overtone of the term ‘semilingualism’ itself invokes expectations of underachievement in the bilingual speaker. Thus, rather than highlighting the apparent ‘deficits’ of bilingual speakers, the more positive approach is to emphasize that when suitable conditions are provided, languages are easily capable of development beyond the ‘semi’ state.

One of the specific issues Bloomfield raised in his comments on the language behavior of members of the Menomini Indians in North America was the frequent mixing of their own language and English. It has been described as ‘verbal salad,’ not particularly appealing but nevertheless harmless, or ‘garbage’ that is definitively worthless and vulgar. Unfortunately, although switching and mixing of languages occurs in practically all bilingual communities and all bilingual speakers’ speech, it is stigmatized as an illegitimate mode of communication, even sometimes by the bilingual speakers themselves. Haugen (1977: 97), for example, reports that a visitor from Norway made the following comment on the speech of the Norwegians in the United States: “Strictly speaking, it is no language whatever, but a gruesome mixture of Norwegian and English, and often one does not know whether to take it humorously or seriously.” Gumperz (1982: 62–63) reports that some bilingual speakers who mixed languages regularly still believe such behavior was “bad manners” or a sign of “lack

of education or improper control of language.” One of the Punjabi–English bilinguals Romaine interviewed said: “I’m guilty as well in the sense that we speak English more and more and then what happens is that when you speak your own language you get two or three English words in each sentence ... but I think that’s ‘wrong’” (Romaine, 1995: 294).

Attitudes do not, of course, remain constant over time. At a personal level, changes in attitudes may occur when there is some personal reward involved. Speakers of minority languages will be more motivated to maintain and use their languages if they prove to be useful in increasing their employability or social mobility. In some cases, certain jobs are reserved for bilingual speakers only. At the societal level, attitudes toward bilingualism change when the political ideology changes. In California and elsewhere in the southwestern United States, for instance, *pocho* and *calo* used to serve as pejorative terms for the Spanish of local Chicanos. With a rise in ethnic consciousness, however, these speech styles have become symbolic of Chicano ethnicity and are now increasingly used in contemporary Chicano literature. Since the 1960s, there has been a political movement, particularly in the United States, advocating language rights. In the United States, questions about language rights are widely discussed not only in college classrooms and language communities but also in government and federal legislatures.

Language rights have a history of being tested in U.S. courtrooms. From the early 1920s to the present, there has been a continuous debate in U.S. courts of law regarding the legal status of language minority rights. To gain short-term protection and a medium-term guarantee for minority languages, legal challenges have become an important part of the language rights movement. The legal battles concerned not just minority language vs. majority language contests, but also children vs. schools, parents vs. school boards, state vs. the federal authorities, and so on. Whereas minority language activists among the Basques in Spain and the Welsh in Britain have been taken to court by the central government for their actions, U.S. minority language activists have taken the central and regional government to court.

The language rights movement has received some support from organizations such as the United Nations, Unesco, the Council of Europe, and the European Union. Each of these four organizations has declared that minority language groups have the right to maintain their languages. In the European Union, a directive (77/486/E EC) stated that member states should promote the teaching of the mother tongue and the culture of the country of origin in the education of migrant workers’ children. The kind of

rights, apart from language rights, that minority groups may claim include protection, membership of their ethnic group and separate existence, non-discrimination and equal treatment, education and information in their ethnic language, freedom to worship, freedom of belief freedom of movement, employment, peaceful assembly and association, political representation and involvement, and administrative autonomy.

However, real changes in attitudes toward bilingualism will not happen until people recognize or, better still, experience the advantages of being bilingual. Current research indicates that there are at least eight overlapping and interacting benefits for a bilingual person, encompassing communicative, cognitive and cultural advantages (adapted from Baker and Prys Jones, 1998: 6–8):

Communicative advantages

Relationships with parents: Where parents have differing first languages, the advantage of children becoming bilingual is that they will be able to communicate in each parent’s preferred language. This may enable a subtler, finer texture of relationship with the parent. Alternatively they will be able to communicate with parents in one language and with their friends and within the community in a different language.

Extended family relationships: Being a bilingual allows someone to bridge the generations. When grandparents, uncles, aunts and other relatives in another region speak a language that is different from the local language, the monolingual may be unable to communicate with them. The bilingual has the chance to bridge that generation gap, build closer relationships with relatives extended family.

Community relationships: A bilingual has the chance to communicate with a wider variety of people than a monolingual. Bilingual children will be able to communicate in the wider community and with school and neighbourhood friends in different languages when necessary.

Transnational communication: One barrier between nations and ethnic groups tends to be language. Language is sometimes a barrier to communication and to creating friendly relationships of mutual respect. Bilinguals in the home, in the community and in society have the potential for lowering such barriers. Bilinguals can act as bridges within the nuclear and extended family, within the community and across societies.

Language sensitivity: Being able to move between two languages may lead to more sensitivity in Communication. Because bilinguals are constantly monitoring which language to use in different situations, they may be more attuned to the communicative needs of those with whom they talk. Research suggests that bilinguals may be more empathic towards listeners’ needs in communication. When meeting those who do not speak their language particularly well, bilinguals may be more patient listeners than monolinguals.

Cultural advantages

Another advantage of being a bilingual is having two or more worlds of experience. Bilingualism provides the opportunity to experience two or more cultures. The monolingual may experience a variety of cultures; for example, from different neighbours and communities that use the same language but have different ways of life. The monolingual can also travel to neighbouring countries and experience other cultures as a passive onlooker. However, to penetrate different cultures requires the language of that culture. To participate and become involved in the core of a culture requires a knowledge of the language of that culture.

There are also potential economic advantages to being bilingual. A person with two languages may have a wider portfolio of jobs available. As economic trade barriers fall, as international relationships become closer, as unions and partnerships across nations become more widespread, all increasing number of jobs are likely to require a person to be bilingual or multilingual. Jobs in multinational companies, jobs selling and exporting, and employment prospects generated by translational contact make the future of employment more versatile for bilinguals than monolinguals.

Cognitive advantages

More recent research has shown that bilinguals may have some advantages in thinking, ranging from creative thinking to faster progress in early cognitive development and greater sensitivity in communication. For example, bilinguals may have two or more words for some cactus object and idea; sometimes corresponding words in different languages have different connotations. Bilinguals are able to extend the range of meanings, associations and images, and to think more flexibly and creatively. Therefore, a bilingual has the possibility of more awareness of language and more fluency, flexibility and elaboration in thinking than a monolingual.

It would be misleading to suggest that there is no disadvantage to bilingualism. Some problems, both social and individual, may be falsely attributed to bilingualism. For instance, when bilingual children exhibit language or personality problems, bilingualism is sometimes blamed. Problems of social unrest may unfairly be attributed to the presence of two or more languages in a community. However, the real possible disadvantages of bilingualism tend to be temporary. For example, bilingual families may be spending significantly more of their time and making much greater efforts to maintain two languages and bring up children bilingually. Some bilingual children may find it difficult to cope with the school curriculum in either language for a short period of time. However, the individual, cognitive, cultural, intellectual, and economic advantages bilingualism brings to a person make all the effort worthwhile.

A more complex problem associated with bilingualism is the question of identity of a bilingual. If a

child has both a French and an English parent and speaks each language fluently, is he or she French, English, or Anglo-French? If a child speaks English and a minority language such as Welsh, is he or she Welsh, English, British, European, or what? It has to be said that for many bilingual people, identity is not a problem. Although speaking two languages, they are resolutely identified with one ethnic or cultural group. For example, many bilinguals in Wales see themselves as Welsh first, and possibly British next, but not English. Others, however, find identity a real, problematic issue. Some immigrants, for instance, desperately want to lose the identity of their native country and become assimilated and identified with the new home country, while some others want to develop a new identity and feel more comfortable with being culturally hyphenated, such as Chinese-American, Italian-Australian, Swedish/Finnish, or Anglo-French. Yet identity crises and conflicts are never static. Identities change and evolve over time, with varying experiences, interactions, and collaborations within and outside a language group.

Bilingualism is not a static and unitary phenomenon; it is shaped in different ways, and it changes depending on a variety of historical, cultural, political, economic, environmental, linguistic, psychological, and other factors. Our understanding of bilingual speakers' knowledge and skills will grow as research methodology is defined and refined and our attitudes toward bilingualism change to the positive.

Bilingualism and Second Language Learning

T K Bhatia, Syracuse University, Syracuse, NY, USA

Introduction

There is a widespread perception in monolingual societies, particularly in the United States, that bilingualism is a rare and exceptional occurrence in communication. By contrast, from a global perspective,

bilingualism is a world-wide phenomenon. In fact, global communication is often carried out through a speaker's second, third, or even fourth language. According to David Crystal (1997) approximately two-thirds of the world's children grow up in a bilingual environment which, in turn, leads to adult bilingualism/multilingualism. However, childhood bilingualism is not the only reason for adult bilingualism. A host of different factors (such as marriage, religion, education, linguistic plurality of a particular

region, migration, jobs, government policies, urbanization, etc.) also lead to adult bilingualism. How, then, do humans become bilingual? Is adult second-language learning different from child-language learning? Is bilingual-language acquisition different from monolingual-language acquisition? Is early bilingualism different from late bilingualism? Does second language learning have adverse cognitive effects on children? And how are two (or more) languages represented in the brain? This article attempts to answer these and other questions concerning bilingual language learning and use.

Key Concepts

Before discussing language development among bilinguals, it is crucial to give an overview of key fundamental concepts concerning language development in children and adults. Also, it should be mentioned that the term ‘second language learning’ is used in a wider sense to include the learning of any additional language during a period ranging from childhood to adulthood. An additional language may be a language of the country or spoken outside the country (i.e. foreign language).

Acquisition vs. Learning

A child’s process of learning languages is different from an adult’s process. A child can learn any language relatively effortlessly, while the same task becomes rather challenging for adults. For this reason, some second language researchers (Krashen, 1985) distinguish between two types of mechanisms in language development: a subconscious process resulting in tacit knowledge of the language (i.e., ‘language acquisition’), and a more conscious process (i.e., ‘language learning’). While children go through the former process, adults undergo the latter in their quest to become bilingual.

The Critical Period Hypothesis and Its Biological Basis

In addition to degree of effort, it has been frequently observed that even very proficient bilinguals fall short of being perfect bilinguals. In spite of the complete mastery of syntax, their speech is marked by traces of the first language accent. Similarly, it is also shown that in spite of considerable effort and motivation, the ultimate attainment of some grammatical structures by adults is seldom achieved. To explain these and other differences in language acquisition and recovery from aphasia Lenneberg (1967) proposed the “critical period hypothesis,” which is sensitive to age. This hypothesis claims that there is a period in the

maturation of human organism, lasting from two years to puberty, in which nearly effortless and complete language acquisition is possible. Afterwards, this hypothesis notes, language learning requires more effort and motivation, largely because of a loss of brain plasticity resulting in the completion of the lateralization of the language function in the left hemisphere. Recent research claims have additionally shown that there are different critical periods for different grammatical structures of language. Since the accent (phonetics and phonology) of a second language is the most difficult to attain, the critical period for phonetics and phonology (approximately from five to seven years) is earlier than that for morphology and syntax. See Johnson and Newport (1991) and Bhatia and Ritchie (1999) for details.

Access to Universal Grammar (UG)

Children are born to acquire human languages. Regardless of gender, race, ethnicity, or nationality, every normal child is capable at birth of acquiring any human language. In theoretical studies following from the Chomskyan mentalistic framework, this innate ability is termed the access to universal grammar (UG). In this case, a child has full access to universal grammar, whereas an adult has either limited or no access. These and other universal principles of grammatical structures and principles of learning largely lead a child’s language development. The role of parental input then becomes to trigger an appropriate value for innately given or set parameters, specific to the language to which the child is exposed. One such parameter, called the ‘head parameter,’ describes how a child does not have to even learn the specific word order of his/her language, but only has to choose between already specified values – head-initial or head-final – based on the nature of the input language. Children begin to learn to set parametric values even from the one-word stage. A Japanese child learns to choose the head-final system, whereas an English-speaking child chooses the head-initial value. These principles are generally referred to as a child’s language acquisition device (LAD).

Input and Learning Environment: Natural vs. Unnatural Settings

Usually children become bilingual or multilingual in a natural way. A normal child can become a fluent bilingual by the age of five, for instance, without any formal training. In the process of acquiring a language, the role of input (motherese, etc.) or imitation is important but limited. Children do not learn a language by mindlessly imitating the input provided by mothers or caretakers. That is, while the role

of parental input cannot be ruled out, language acquisition studies show that neither motherese nor imitation plays a significant role in a child's language development. Instead, this burden is carried by the child himself/herself. Research on child-language acquisition reveals that the child learns the language by using the 'rule formulation strategy.' For instance, an English-speaking child learns on his/her own that by the addition of the inflection '-ed' to a verbal stem, one generates the corresponding past tense form of the verb. In this process, the child over-generalizes and produces utterances such as 'I go-ed' [go-PAST]. Even after being corrected [i.e. provided negative evidence] by the mother or caretaker that the child meant 'I went' [go.PAST], the child still does not reject the rule s/he has formulated in his or her mind and which s/he still produces in utterances such as 'I went-ed' [go.PAST-PAST]. The role of the adult is thus to prevent the child's grammar from overgeneralization. In other words, the child has an innate capacity to acquire languages in an environment which is termed a 'natural' environment, whereas, by contrast, adults and school-age children learn language in formal settings such as schools and colleges through a formal instructional method.

Defining and Measuring Bilingualism

What is bilingualism and who is bilingual? Defining and measuring bilingualism is a very complex task due to the number and types of input conditions, biological, socio-psychological, and other non-linguistic factors that can lead to a varying degree of bilingual competencies. In short, there is no widely-accepted definition or measures of bilinguals.

Instead, a rich range of scales, dichotomies, and categories are employed to characterize bilinguals. If a bilingual can understand but cannot speak a second language, such an individual is called a receptive bilingual, whereas a productive bilingual demonstrates a spoken proficiency in two languages. If the second language is acquired in a natural setting before the age of five that individual is termed an early bilingual, in contrast with a late bilingual who learns his second language after the age of five either in home or in schools. Labels such as fluent vs. non-fluent, functional vs. non-functional, balanced vs. unbalanced, primary vs. secondary, and partial vs. complete refer, either to a varying command in different types of language proficiency (e.g., spoken, listening, writing, etc.), or an asymmetrical relationship (dominance) between two languages. A compound vs. coordinate bilingual refers to the way two languages are processed in the brain. The list is by no means exhaustive. Other major distinctions such

as simultaneous vs. sequential are discussed in the next section. Similarly, bilingualism can be viewed from individual, societal (attitudes towards bilingualism), and political (i.e., government policies toward bilingualism) perspectives.

In general, a bilingual person demonstrates many complex attributes rarely seen in a monolingual person. For that reason, a bilingual is not equivalent to two monolinguals, but something entirely different. This working definition of bilingualism is offered by Bloomfield (1933), who claimed that a bilingual is one who has a native-like control of two languages, i.e., a balanced bilingual (see Grosjean 1982 or Edwards, 2004 for more details).

Patterns and Mechanisms in Bilingual Language Development

Providing either a natural environment or inputs in monolingual/dominant language speech communities is not a challenging task. The same is also true for those societies where social and political systems are conducive to bilingualism. For instance, in India, where bilingualism is viewed as natural, approved by society, and further nurtured by government language policies, linguistic groups and communities do not need to take any special measures to assure that their children receive input from two languages. In sharp contrast, in societies where bilingualism is not valued or where the language of a minority is distinct, it becomes imperative for families to plan meaningful strategies to ensure the smooth exposure to the family language. One such strategy that families employ in this second setting, described by Bhatia and Ritchie (1999) as "discourse allocation," restricts the use of one language to one social agent or social setting and the other language to other social situations. The various manifestations of such strategies are the following: (a) one-parent/one-language (e.g., the child's mother speaks one language and, the child's father speaks the other. This strategy was employed by Leopold (1939–1949) in his classic study of bilingual language development of his daughter, Hildegard; (b) one-place/one-language (e.g. speaking one language in the kitchen and the other elsewhere); (c) a language/time approach; and (d) a topic-related approach. Although the discourse allocation approach is better than providing no input and thus raising a monolingual child, it leads to different patterns in bilingual language development than developing bilingualism in a natural setting. For instance, during the early stages of Hildegard's bilingualism, she developed a rule that fathers speak German and mothers speak in English.

Childhood Bilingualism

Other factors such as age and amount of exposure to the two languages also result in differences in the pattern of childhood bilingualism. The distinction between simultaneous and sequential bilinguals in research on bilingual language acquisition is based on age and the degree of exposure to two languages. When the child is exposed to two languages to more or less the same degree from birth onward, the pattern of language development is referred to as simultaneous, whereas sequential bilingualism describes the attainment of one language first and the second language later, preferably before the age of seven. Similarly, the term late bilingual is used for those sequential bilinguals who acquire their second language at a relatively younger age than adults learning a second language. Although there is unanimous agreement among researchers about the validity of the simultaneous and sequential bilinguals, there is no consensus among scholars about the exact line of demarcation between the two. See McLaughlin (1984) and De Houwer (1995) for either theoretical or methodological grounds.

One of the most intriguing aspects of the childhood bilingualism is how children learn to separate the two languages, particularly in a natural setting (i.e., a simultaneous bilingual) in initial stages. After all, when parents provide input, they do not tag or prime their input with a language identification label. Even if parents go to the absurd length of identifying the language of each word or sentence they use, these labels are semantically empty for children. Furthermore, bilingual parents unwittingly make the task of separating the two languages even harder for children because of their normal tendency to mix two languages. In short, a child is provided with three distinct types of linguistic inputs: two languages, each in an unmixed/pure form, and one with a mixture of two languages. Given this state of affairs, how does the child learn to separate the two languages in question? This task is not challenging for a monolingual child because only one language serves as a source of input. The two hypotheses which attempt to shed light on this question are the unitary system hypothesis and the dual system hypothesis.

According the unitary system hypothesis (Volterra and Taeschner, 1978), the child undergoes three stages before s/he is able to separate two input languages. During the first two stages, the child experiences confusion. During the first stage, s/he is unable to distinguish the two lexicons and grammars of the linguistic systems. At this stage, they have a single lexicon made up of items drawn from the lexicons of both languages. Hence, no translational equivalents

or synonyms are found in their vocabulary. Volterra and Taeschner claim that their two bilingual subjects at the ages of 1 year 10 months and 1 year 6 months had a hybrid list of 137 words with no translational equivalents. During the second stage, the child slowly learns to separate the two lexicons, but is still unable to separate the grammatical systems. Cross-linguistic synonyms emerge, but the child applies the same set of syntactic rules to both languages. It is only during the third stage that the child becomes capable of separating the two sets of vocabularies and grammars. Findings of recent research reveal that the unitary system hypothesis cannot sustain the scrutiny of the succeeding research and the evidence motivating the three stages of bilingual language development is full of shortcomings and contradictions both on methodological and empirical grounds.

The dual system hypothesis states that bilingual children, based on their access to Universal Grammar and language specific parameter setting, have the capacity of separating the two grammars and lexical systems right from the beginning. A wide variety of cross-linguistic studies (e.g., different input conditions – one parent/one language and mixed input condition; and different word order types) lends support to this hypothesis. For instance, in a study devoted to the language development of a Hindi-English bilingual child, it is clear that at age 2, the child is capable of developing two distinct lexicons using a syllabification strategy. At the age of 1 year 7 months, two different word orders develop – SVO [subject-verb-object] for English and SOV for Hindi. For a more detailed treatment of the shortcomings of the unitary system hypothesis and the strengths of the dual system hypothesis, see Bhatia and Ritchie 1999: 591–614.

Another fascinating feature of bilingual speech is that, not only are bilinguals capable of keeping the two linguistic systems separate, but they often mix them either within a sentence or inter-sententially. This behavior is often termed ‘code-mixing’ or ‘code-switching’ in sociolinguistic literature. Depending upon the theoretical and empirical objectives of their research, some researchers do not distinguish between the two terms and use them interchangeably; for those researchers who distinguish between the two, the code-mixing refers to intra-sentential mixing while the term code-switching refers to the intersentential mixing in bilinguals. Both bilingual children as well as adults show this behavior. What explains this behavior of language mixing? Earlier research attempted to explain it in terms of the language deficiency hypothesis: it was claimed that bilinguals in general and children in particular have language gaps. As claimed by the unitary system hypothesis the lack

of synonyms compels them to mix the two lexical systems during stage I. Similarly, stage II yields the mixing of two language systems due to confusion. In other words, the lack of proficiency in either one language (i.e., the absence of balanced bilingualism) or both languages (i.e., semi-bilingualism) leads to mixing.

The language augmentation hypothesis is capable of offering deeper insights into the bilingual mixing behavior. As it has been shown earlier in the discussion of the dual system hypothesis, children do not go through the initial stages of treating the two linguistic systems as if they were one system, but begin to distinguish them immediately. The consideration of optimization leads bilinguals to mix language with an aim to get maximum mileage from the two linguistic systems at their disposal. An analogy drawn from the beverage industry further explains this point. The separation of juices (e.g., apple vs. orange juice) renders two distinct tastes. However, if one mixes the two juices, the result is a new taste, a distinct from the two pure juices. The same is true of bilingual language mixing. Research on the linguistic and socio-linguistic motivations for language mixing both in children and adults shows that such considerations as semantic domains and semantic complexity (an item less complex or salient in one language), stylistic effects, clarification, elaboration, relief strategy (i.e., a linguistic item is temporarily unavailable in one language), interlocutor's identification, discourse strategies of participants/topics, addressee's perceived linguistic capability and speaker's own linguistic ability, and other complex socio-psychological reasons, such as attitudes, societal values, and personality, prompt bilinguals to mix two languages. The list of motivations is by no means exhaustive (see Bhatia and Ritchie, 1996, for more details).

Adult Bilingualism: Second Language Learning

In contrast to sequential childhood bilingualism, adults who learn a second language after they have learned their mother tongue experience the learning of a second language as a laborious and conscious task. As pointed out earlier, unlike children who are able to universally and uniformly acquire native competency in their mother tongue, adults rarely achieve native-like competency in their second language. Depending on the level of their motivation and hard work, adults can learn a second language with varying degrees of competence. However, there comes a point during the second language learning that even the most talented learner cannot pass the stage of 'fossilization.' This stage is marked with second language errors which no amount of training can

correct. For these reasons, second language (L2) learning is viewed as fundamentally different from first language (L1) acquisition. The hypothesis which aims at accounting for these differences between the child and the adult language is termed the fundamental difference hypothesis.

In spite of the asymmetrical relation between L1 and L2 learning, one should not draw a conclusion that there is nothing in common between the two. What is common between L1 and L2 learners is that both undergo stages of language development. In other words, like L1 learners, in the process of grammar construction, L2 learners undergo stages of development: the intermediate stages of grammar development between the initial stage and the ultimate stage are termed interlanguage grammars. Take the case of the development of negation in English L1 and L2 learners. The grammar of negation in L2 learners of English shows the same stages of development as in L1 English learners – Stage I: the sentence-initial placement of negation; Stage II: preverbal placement of negation with no auxiliary verb; and Stage III: preverbal placement of negation with an appropriate auxiliary verb.

Native Language Influence and Dominance

An important way in which L2 learning is different from L1 learning is the influence of the mother tongue on second-language learning. The mother tongue or L1 plays an important role in the process of L2 acquisition. Research on grammatical errors of L2 shows that L2 learners transfer the grammatical rules – phonetic, phonological, morphological, and syntactic rules – of L1 to their second language. An English-speaking learner of Hindi has difficulties in hearing and producing a four-way contrast between Hindi aspiration and voicing contrast (i.e., unvoiced unaspirates, unvoiced aspirates, voiced unaspirates, and voiced aspirates).

It would be a gross simplification to claim that L2 learners transfer all grammatical features of L1 to L2. Adult learners possess a relatively higher level of logical and cognitive ability than do children; therefore, these qualities color their second language learning. For instance, English-speaking learners of Hindi will not translate there in these sentences:

1. There is a chair in the room
2. The chair is over there

in an identical way (i.e. by choosing the remote locative adverb in both cases). Similarly, it would be an oversimplification to claim that childhood bilingualism is free from the dominance relationship between the two languages. Not only does the mother tongue

influence second language acquisition in children, it also affects their school achievement.

Approaches to Second Language Learning

In adult language acquisition research, the term second language is used in a wider sense to include both the acquisition of a second language which may or may not be foreign to a country. However, in the context of language teaching the distinction between the two is made to highlight major differences in the learning aims, teaching methods, and the achievement levels to be attained.

A number of approaches have been developed to facilitate the learning of second/foreign languages. Some of the following are notable:

1. Grammar-translation method: Following the tradition of teaching classical languages such as Greek, Latin, and Sanskrit, this method places emphasis on memorization and rote learning. Learners memorize nominal and verbal paradigms of the second language and translate L1 into L2 or vice versa. Very little emphasis is placed on developing spoken proficiency in the foreign language, while reading and written comprehension receives overwhelming importance. This method is perhaps the oldest method of language teaching which dates back to the 19th century.
2. The direct method: Also known as oral or natural methods, it departs from the grammar-translation method in three important respects: one, memorization receives a back seat in the learning of the second language; two, special emphasis is placed on acquiring spoken and listening competencies; and three, the introduction of the target language is free from any reference to the native language of learners. Native language is never used as a tool to explain either grammar or other intricacies of the target language usage. This model attempts to simulate the native speaker environment of the target language. However, in actual practice there are severe constraints on replicating the natural setting of the native speaker's learning environment in an actual classroom setting.
3. The audio-lingual method is a byproduct of World War II during which the United States experienced an urgent need to quickly train its troops in foreign languages for overseas military operations. An emphasis is placed on spoken and listening competencies, rather than on written ones.
4. The structural method: In order to speed up the acquisition of foreign languages, insights of structural linguistics were applied to language teaching. This method exposes learners to different structural patterns and transformation drills.

Audio-lingual structural models assume that L2 is acquired through imitation. The discussion in the key concept section shows the limitation of this model. A number of other methods such as the natural approach and 'suggestopedia' have been proposed, but the fact remains that no method has a grip on the complexity involving learning a second language.

Bilingual Education: Additive vs. Subtractive Bilingualism

Teaching children a school language, particularly if the school language is different from the child's home language, is one of the major challenges for bilingual education programs. Bilingual education programs in America aim at minority students learning English. Such programs have attracted a great deal of controversy on the basis of their merit and outcome. While there is rapid growth of bilingual education programs in the United States, the aim of such programs is not always to introduce additive bilingualism which ensures the maintenance of the child mother tongue, while learning the school/dominant language. A large number of bilingual education programs in the United States aim at subtractive bilingualism. In other words, while they offer children a transition to learning the school/majority language, in that process they do not ensure the maintenance of the child's mother tongue.

In contrast, the language policies of bilingual nations such as India, Canada, and Switzerland are very conducive to the promotion of language rights for minority languages. The government of India, for instance, favors the advancement of linguistic diversity and pluralism by the introduction of the Three Language Formula, which calls for trilingualism in education. In addition to learning two national languages, Hindi and English, students are expected to learn a third language beyond their native tongue. For example, in northern India, students are expected to learn one of the four Dravidian languages (Tamil, Telugu, Kannada, and Malayalam) from southern India.

While bi- or multi-lingual education programs like India's do not view bilingualism in general and the maintenance of minority languages in particular as a threat to national integration, this is not the case with bilingual education in the United States. U.S. educational policies are not conducive to linguistic and cultural diversity.

A notable feature of the Canadian bilingual education program is termed the language immersion program. Introduced in the 1960s in Quebec, the program was introduced at the request of the English-speaking minority to provide their children

a high level of proficiency in schools in the dominant language of the region, French. Children were immersed in schools in the second language of students (i.e., French) in which children used their mother tongue to communicate with a bilingual teacher who would reply in French. This process leads children from what Cummins (1981) calls basic interpersonal communication skills (BICS) proficiency to cognitive-academic language proficiency (CALP) in the school language. BICS refers to the language proficiency level of students with restricted vocabulary and simpler syntax, whereas CALP requires a type of proficiency suitable for academic pursuits – a developed vocabulary and sufficiently complex syntax suited for abstract and analytical thinking. The success of the Canadian language immersion model continues to generate enthusiasm and controversy in bilingual education in the United States.

Socio-Psychological Factors

Successful language learning not only depends on teaching methods but also on learners' motivation, intelligence, opportunities, and other factors, such as their attitude toward the target language and culture. Keeping in mind the motivation and the learners' attitudes, there are two types of learners: instrumental and integrative learners. Instrumental learners, who learn a language for the purpose of gaining external rewards (monitory gains, good jobs, etc.), however, tend to be less successful learners than integrative learners, who have a positive attitude toward the culture of the target language. Psychological factors such as the affective filter (Krashen, 1985) either inhibit or promote the learning of a second language: negative influences such as anxiety, lack of self-confidence, and inadequate motivation can create serious obstacles to successful language learning. Due to a lack of self-esteem and a higher level of performance anxiety, minority children tend to raise the affective filter, which results in the reduction of comprehensible input. Consequently, it takes a toll on their progress in language acquisition. Similarly, since adults show more self-consciousness than children, they put themselves in a disadvantageous position in terms of language acquisition.

Effects of Bilingualism

Does bilingualism have an adverse linguistic and cognitive effect, particularly on children? Earlier research in the United States pointed out that exposing children to more than one language during their childhood leads them to semi-bilingualism and confusion. Crowding their brain with two or more languages,

this research suggested, not only leads children to linguistic deficiency, both in competence and performance levels (semi-lingualism, stuttering, etc.), but also to a wide variety of cognitive and psychological impairments such as low intelligence, mental retardation, left-handedness, and even schizophrenia.

Research by Peal and Lambert (1962), however, put to rest such a negative view of bilingualism: their findings and the work of succeeding researchers provide ample evidence that these negative conclusions of earlier research were premature, misguided (biased toward immigrant communities), and unnecessarily pessimistic. Solid on methodological grounds, Peal and Lambert's study revealed a positive view of bilingualism, including the conclusion that bilingual children demonstrate more cognitive flexibility than monolinguals. Contrary to previous studies, bilinguals performed better than monolinguals in both verbal and non-verbal measures. The study, which was conducted in Montreal, was revolutionary in its own right, changing the face of research on bilingualism forever (see Hakuta, 1985: Chap. 2 for details). This study has been replicated in a number of countries confirming the positive effects of bilingualism.

Conclusions

A number of diverse and complex conditions and factors lead to life-long bilingualism. These factors – biological, social, psychological, and linguistic – account for a varied pattern amongst bilinguals, witnessed around the world. Thus, a bilingual is neither two monolinguals in the brain, nor are two bilinguals clones of each other. These complexities indicate why no theory of language learning and/or teaching is capable of explaining bilingual verbal behavior and the mechanisms leading to bilingual language development.

Jerome Bruner is a pre-eminent, powerfully influential, and multiply pioneering psychologist whose studies have touched on language in many ways.

Born in New York City of nominally observant Jewish parents, he was blind for the first two years of life. His father, a watchmaker, died when he was 12, after which his family moved about, and he developed his interest in sailing. He attended Duke University (B.A., 1937), and went to Harvard for graduate study in psychology (Ph.D., 1941). He served in the U.S. Army Intelligence Corps in World War II, applying his knowledge of propaganda and public opinion. He then joined the Harvard faculty, doing experimental psychological research on the dependence of perception on motivation (the 'New Look' studies). He carried out an enormously influential series of studies on the acquisition of structured cognitive categories, involving the grouping of instances on the basis of values of defining attributes. He founded and directed the Center for Cognitive Studies in the 1960s, leading the way toward the field's mentally realistic engagement with information processing. He left Harvard for the Watts Professorship of Experimental Psychology, at Wolfson College, Oxford University, in 1972, personally sailing across the Atlantic to assume his new role, and then returning to the United States in 1979. He has subsequently taught at the New School for Social Research (New York City) and

the New York University School of Law. His research interests progressed from cognitive to developmental and educational psychology, where his thinking has galvanized our understanding of pedagogical practice, and then on to cultural and narrative psychology, providing specimen studies exemplifying another novel and productive paradigm for human studies.

His abiding interest in language began with his work on wartime propaganda and public opinion, more or less by-passed his perceptual experiments, and continued with his analyses of conceptual categorization. Despite personal contacts with George A. Miller, Noam Chomsky, Roman Jakobson, and Roger Brown, he never became enamored of the structural properties of syntactic or phonological grammars. For instance, it was Brown who added a 65-page appendix to *A study of thinking*, indicating how attributes and categorizations are involved in speech and linguistic meaning.

He became interested in language development, as epitomizing a symbolic, in contrast to iconic or enactive, system of representation and cultural 'amplifier' of reflective, in contrast to sensory or motoric, capacities. From language as an instrument of thought, based on semantic representation, he went on to treat language development in terms of communicative (or pragmatic) function. This perspective allowed him to combine prior American pragmatic and generative influences, with Oxfordian 'ordinary language' work on Austinian illocutionary acts, as well as Tinbergen's ethology – in his delineation of the ontogenesis of speech acts. He went on to the formulation of

the Language Acquisition Support System, through which speakers became participants with particular linguistic communities or subcommunities. In this way, he could emphasize not only cultural influences, but also narrative structures and processes. He based his account of stories on Kenneth Burke's pentad (Agents, Actions, Goals, Instruments, Settings – plus Trouble!), as well as other structural accounts and hermeneutic modes of human intentionality. Narratives, thus conceived, have properties that allow construction of personal selves/identities, as well as human institutions (such as schools and legal systems), and provide for the dynamics of individual development/aging and or human history (the passing forward of culture).

His prolific career has provided contributions sufficient to suggest several approaches to the role of language in the human sciences, but reflects a general trend from the application of his original experimental psychology to his more recent anthropological/interpretive stance. He has managed to combine an engagement in current political, educational, and legal issues, as they have become crucial over the decades, with a principled perspective stemming from meaning-based psychological research and theory – which he has helped shape and vitalize. His

has not been a 'school of psycholinguistics,' but rather a schooling of psychological engagement in human language.

Bühler, Karl

M Bednarek, University of Technology, Sydney, Australia

© 2006 Elsevier Ltd. All rights reserved.

Karl Bühler (see **Figure 1**) was born in Germany (Meckesheim) in 1879 and, after gaining a doctorate in philosophy and medicine, started work as an assistant to Oswald Külpe, a psychologist in Würzburg. Later he worked as a professor of psychology in Dresden and Vienna (1922–1938), before having to emigrate to the United States in 1938, where he lived in Los Angeles from 1945 until his death in 1963.

In linguistics Bühler is most famous for his work on deixis and on language function, but he also published work on developmental psychology, language comprehension, and human cognition as well as on other linguistic phenomena such as phonology, syntax, morphology, and stylistics.

Bühler postulated four axioms for linguistics, which were concerned with (1) the organon model of language, (2) the sign status of language (by virtue of *abstract* features), (3) the field structure of

language (Bühler united von Humboldt's dichotomy of *ergon* and *energeia* and de Saussure's distinction between *langue* and *parole* in his *Vierfelderschema* of language as *Sprechhandlung*, *Sprachwerk*, *Sprechakt*, and *Sprachgebilde*), and (4) the fact that language is a system of two 'classes' (*Zweiklassensystem*), namely semantics and syntax. Of these four axioms, it was especially the organon model that was influential.

The Organon Model

In his *Organonmodell* Bühler took up Plato's proposal to explain language by virtue of the metaphor of language as a tool (Greek *órganon*) that serves distinct functions in society. He distinguished between three functions: *Darstellung* ('representation'), *Ausdruck* ('expression'), and *Appell* ('vocative', 'appellative'). In very simple terms, language may be used for the representation of things (*Dinge: Darstellung*), for the expression of the speaker's inner feelings/states (*Sender: Ausdruck*), and for influencing the hearer's behavior (*Empfänger: Appell*). The linguistic sign is hence functionally very complex: it is a

Figure 1 Karl Bühler. With permission of the Archiv der Universität Wien.

symbol by virtue of its representational function, a *symptom* (sign, index) by virtue of its dependence on the sender, and a *signal* by virtue of its appeal to the hearer. In a given instance, one of these functions may dominate the others: *Darstellung* dominates in scientific language, *Ausdruck* in poetic language, and *Appell* in military language, but this does not mean that the other functions are not present as well (Bühler speaks of *Dominanzphänomene*). Thus, an expression such as *es regnet* ('it's raining') denotes a meteorological event (*Darstellung*). But by uttering it with different intonations, the speaker can also express his/her feelings (*Ausdruck*) or appeal to someone not to forget to bring an umbrella (*Appell*) (1982: 46). Because of Bühler's occasionally imprecise style of writing, aspects of this model remain much-discussed in European linguistics. For instance, it is not clear to what extent means of *Ausdruck* are employed intentionally or subconsciously and to what extent they are conventionalized. Although some of his examples include conventional and intentional expressions, *Ausdruck* is defined by him as "freie oder gehemmte Entladung von Affekten" (1982: 352), i.e., the free or inhibited discharge of emotions, which seems to more or less *subconsciously* 'mirror' the speaker's mental state or personality traits (Auer, 1999: 33). From a strict viewpoint, this function thus does not concern linguistics (Konstantinidou, 1997: 36; cf. also Péter, 1984: 245; Stankiewicz, 1964: 239f.); however, Bühler's

expressive function has also been interpreted as referring to intentional linguistic communication.

The 'Field Theory' of Language

Bühler also developed his own contextual language theory, the *Zweifelderlehre* ('two-field theory'). Signs, he said, are not isolated entities but always occur in context, in a 'field' that can be deictic (*Zeigfeld*) or symbolic (*Symbolfeld*). As such, linguistic signs function as *Feldgeräte* ('field tools'). Representational symbols can be interpreted solely with the help of the *Symbolfeld*, but in order to assign meaning to utterances containing deictic signals (*Zeigwörter*), hearers need the extralinguistic context (the *Zeigfeld*). What is designated by expressions such as *here, there, I, you* changes according to the position of the speaker. Thus, it is the *I, now, and here* that establishes the deictic center (Bühler calls it the *Ich-jetzt-hier-Origo*). The matter is more complicated because there are several *modi* of pointing toward the context of utterance: *ad oculos* (reference to components of the current context), *anaphorisch* (reference to textual components), and *am Phantasma* (reference to fictional worlds).

Bühler's contribution to linguistics is enormous: apart from crucially influencing linguistic research (especially the Prague School) before World War II, his work has been of great importance in linguistics since the 'pragmatic turn' in the 1970s, although he failed to gain the deserved attention upon his emigration to the United States. His *Organonmodell* has been immensely significant in that it influenced the establishment of derived functional models from Roman Jakobson to Dell Hymes and M.A.K. Halliday. He is still being reinterpreted and analyzed within modern linguistics (e.g., Kubczak, 1984; Péter, 1984; Auer, 1999). Similarly, his comments on deixis, morphology, and metaphor have provided a stepping stone for modern approaches in these fields. His estate is currently being reorganized by the FDÖP (*Forschungsstelle und Dokumentationszentrum für österreichische Philosophie*).

Class Language

A Luke, University of Queensland, Brisbane, Australia
P Graham, University of Waterloo, Canada

The relationship between language and social class is a key theoretical and empirical issue in critical discourse studies, ethnography of communication, and sociolinguistic research. It has been a focal point for postwar and current policy in language planning, and language and literacy education. The central questions of a class analysis of language were stated in Mey's (1985) proposal for Marxian pragmatics: 'Whose language' counts? With what material and social consequences? For which communities and social groups? Central concerns are how language factors into the intergenerational reproduction of social and economic stratification, and how communities, families, schools, the media, and governments contribute to "linguistic inequality" (Hymes, 1996). Yet current research continues to table and debate contending definitions of language and social class as social and economic phenomena.

Marx viewed language as an intrinsic characteristic of human 'species being,' as a form of mental and material labor. The "language of real life," he argued, is "directly interwoven" with "material activity and... mental intercourse" (Marx and Engels, 1845/1970: 118). This "mental production" is "expressed in the language of politics, laws, morality, religion, metaphysics etc. of a people." 'Sense experience,' the work of the eye and ear, was the basis not only of science, but of communal and social life (Marx, 1844/1964: 160–166). At the same time, Marx's (Marx and Engels, 1845/1970: 37) classical definition of ideology as a 'camera obscura' established the centrality of language in the distortion and misrepresentation of social and economic reality in social class interests (see **Marxist Theories of Language**).

Marxist theory establishes three critical traditions in the analysis of language and class. These are: (1) the analysis of language as a form of class-based social action and consciousness; (2) the analysis of social class and linguistic variation; and (3) the

analysis of language as the medium for power and - control, ideology, and truth in specific linguistic and capital markets (see **Power and Pragmatics**).

Language as Social Action and Class Consciousness

The prototypical class analysis of language was undertaken by Voloshinov (1973) (see **Voloshinov, Valentin Nikolaevich**). Language was conceptualized as a marker of class consciousness and a medium of class struggle. According to models of heteroglossia and 'multivocality,' each utterance and text is a revoicing of previous historical speakers and writers. The ideological content and social functions of each speech act or speech genre bear their own material historical origins. That is, they are produced and reproduced by and through social and economic "conditions of production" (Fairclough, 1992). By this account, face-to-face language exchanges are instances of class conflict and ideological difference, where class-located social actors bring to bear distinctive material interests and discourse positions. The point of such analysis is to extend the notion of the situated speaking and writing subject, to a closer sociological and economic analysis of that positionality. Contemporary work in critical discourse analysis supplements class analysis with attention to the linguistic construction of gender, race, sexual preference, and other forms of social identity ideology, and position (e.g., Lemke, 1995).

If utterances and their use are indexical of ideology and social class consciousness, what might this mean for differing cultural groups, communities, and their historical practices? Following Vygotsky (see **Vygotskij, Lev Semenovitch**), Luria (1982) argued that the cognitive uses of the 'tool' of language were mediated by one's social relations, cultural practices, and material conditions. In his studies of the Uzbeks, Luria made the claim that particular forms of cognition and consciousness, what Marx referred to as capacity for the "production of ideas," were linked to cultural practices and material conditions of tool use. The cognitive affordances of language and literacy are

mediated by material economic and social conditions, including class location and cultural history.

In contemporary literacy theory, Paulo Freire also argued for the direct links between language and social class consciousness. Freire's (1972) prototypical work was concerned with the effects of literacy education upon the language and consciousness of the indigenous population and peasantry of postwar Brazil. Bringing together Marxist dialectics with liberation theology, he argued that autocratic governments and education systems constituted "cultures of silence" where marginalized populations were educated in ways that misnamed and misrecognized the world. Freire's work views ideologically distorted language as a mode of class-based false consciousness.

For Freire, critique of class consciousness was achieved through an educational process of 'renaming' the world in ways that demystified power, consciousness, and life, a similar agenda to that of Mey (1985), Chouliaraki and Fairclough (2001) and other contemporary critical linguists. Current agendas for the teaching of 'critical literacy' and critical discourse analysis stand in this Marxist tradition, focusing on the demystification, critique, and reconstruction of ideological language (Luke, 2004).

Linguistic Variation and Social Class

A further concern in the analysis of language and social class is how language variation acts as a marker and instrument of social class, and of racial and other forms of social stratification. A principal concern of sociolinguists in the postwar period has been over the effects of the differential and inequitable spread of economic and social capital on the language minority, postcolonial, and economically marginal communities (Hymes, 1996) (*see Minority Languages: Oppression*). The postwar origins of language planning reflect the impact of colonization, decolonization, migration, and geopolitical conflict upon linguistic retention and stability. The flow of global, regional, and national capital visibly impacts upon language loss, use, and retention (Pennycook, 1998). In the postwar period, sociolinguistic and language planning research has engaged with the effects of the unequal spread and distribution of economic capital upon language loss. Yet attempts to theorize and empirically describe the complex reproductive relationships of language and social class have been debated and contested (*see Linguistic Decolonialization*).

The sociological and sociolinguistic research on U.K. children by Basil Bernstein and colleagues (e.g., Bernstein, 1975) took up this challenge. This work provided an account of the role of language in the

institutional production of stratified levels of educational achievement. Bernstein's argument was that working class students spoke a "restricted code," characterized by embedded and literal meanings, limited command of deixis, and thresholds in technical complexity. Middle-class children, he argued, mastered an "elaborated code" which was fitted for educational success and mastery of academic and scientific discourses. These, he argued, were tied to particular forms of early childhood language socialization and family structure (Bourdieu and Passeron, 1992). Bernstein's work was the object of several decades of controversy. Labov's (2001) studies of urban African-American language registers and non-standard dialects, and Heath's (1983) studies of early class-based language socialization made the case against models of linguistic deficit. Bernstein's model has been defended by systemic functional linguists, who argue that there are indeed elaborated technical registers and contents, specific language domains affiliated with power, some of which particular social classes make explicitly available in early language socialization and educational training (Hasan and Williams, 1996) (*see Codes, Elaborated and Restricted*).

As distinctive sociodemographic speech communities, particular social classes may indeed have different speech patterns, varying in *lingua franca*, register, dialect, accent, and practices of diglossia (*see Register: Overview*). These, further, are affiliated with class-based social ideologies and cultural practices (Fishman, 1991). Ethnographic studies have shown how these variations are made to count in local social networks and institutions (Milroy, 1987). But the social and cultural bases and material consequences of such differences remain localized and contentious. To move past descriptive claims requires a broader sociological theory of social class, of "linguistic markets" (Mey, 1985; Bourdieu, 1992), and of changing media and modes of production and information.

Language as Capital in Linguistic Markets

Classical sociological definitions of social class begin from conceptions of structural economic location and material position. They attempt to define position and power *vis-à-vis* dominant means of production. The tendency of Marxist models is to further affiliate social class with particular 'class consciousness,' of which language, its use and its expression, is a constitutive speech marker. Bourdieu's (1992) sociology began from a view that class position is at least in part structurally determined. But it is also embodied

by human subjects in their 'habitus,' the sum total of socially acquired dispositions.

By this account, the bodily performance of linguistic competence is an element of cultural capital. This capital and affiliated forms of embodied taste, style, and ideology, constitute a key marker of one's social class position and mobility. Linguistic capital is deployed in specific social fields, which constitute 'linguistic markets.' Each market, each institutional context, in turn has variable rules and conventions of exchange whereby linguistic competence and literate proficiency in specific languages is valued or not. There, language use – as class marker and tool – has exchange value and power only in relation to other forms of capital, including social capital (e.g., networks, institutional access), economic capital, formal institutional credentials, artifacts, and so forth.

This is a more complex view of the relationship of language and social class. Language matters, as a primary marker of class, gender, culture, training, education, networks, traditions, and ideological consciousness. Yet like post-structuralist theories of discourse, Bourdieu's model viewed language not just as an index or marker of class position, but as reflexively constituting position and identity, power, and categorical social status. In this way, how language marks class, capital, and power is sociologically contingent, rather than determined by the characteristics of linguistic code or class position per se, or the ostensive power of any given utterance, genre, or text (Luke, 1996). This contingency is dependent on the availability of other forms of capital, and the variable, historically shifting norms, rules, and conventions of particular social institutions, fields of knowledge, and linguistic markets (*see Discourse, Foucauldian Approach*).

Current Issues

One of the principal critiques of postwar sociolinguistics, ethnography of communication, and functional linguistics was that they lacked a sufficient analysis of power, capital, and conflict. Indeed, sociolinguistic models of 'social context,' 'context of situation,' and 'social network' are often based on structural functionalist models of society and culture. The study of language and social class requires the rigorous analysis of social and economic relations within and between speech communities. Current work on language and social class continues to examine how language represents class consciousness, how it is implicated in ongoing issues of class conflict and cohesion, and how its acquisition and use are central to intergenerational production of social stratification of material and discourse resources.

Language variation, diversity, change, and ideology can be systematically linked to social class. Linguistic performance in text and discourse production does indeed have both symbolic and material exchange value, particularly in service- and information-based economies. But this depends upon the complex local economic and institutional formations of particular speech communities. Bourdieu offered a stronger analytic frame for analyzing how language 'counts' in specific institutional, disciplinary, and knowledge fields, and everyday social contexts. He suggested that issues around 'whose language' counts, which classes have power, require a rigorous socioeconomic analysis. Particularly under conditions of late capitalism and globalization, these sociological and sociolinguistic contexts and conditions are under considerable historical transition and challenge.

As the medium of consciousness and labor, language is entailed in the production of ideology, material goods, and social relations. The move in globalized economies towards information- and discourse-based forms of labor raises a number of key challenges to linguistic and ethnographic studies. First, linguistic, semiotic, and discourse competence will have increased significance in productive labor and consumption, shifting social class relations to means of production. Second, social class location and membership is determined by relations to dominant modes of communication, semiosis, and information (Castells, 2000) as much as it might be defined in classical Marxist terms. Finally, the formation of social class identity, ideology, and speech community have become more complex. They are now strongly influenced by forces of mass culture, media, and globalized information flows.

One of the principal claims of post-structuralist and postmodern theory of the past decade has been a breakdown of essential relationships between discourse and social class as a primary analytic category. It is increasingly difficult to analyze social class formation without due consideration of the complexity of cultural, racial, gender, and religious identity and position. Any analysis of language and social class must engage with this complexity. But indeed, any contemporary analysis of class and intersecting categories must engage with the constitutive place of language, text, and discourse.

Classroom Talk

E Hinkel, Seattle University, Seattle, WA, USA

© 2006 Elsevier Ltd. All rights reserved.

Much classroom activity takes the form of talk. In recent decades, studies of teacher and student spoken language in the classroom have been undertaken from a variety of perspectives in applied linguistics, education, ethnography, and ethnomethodology. In particular, the analyses of talk between the teacher and the students, as well as among students, seek to understand how the spoken language and the discourse of the classroom affect learning (including language learning) and the development of sociocultural affiliation and identity (e.g., Watson-Gegeo, 1997).

To a great extent, spoken language and face-to-face interaction constitute the foundational aspects of both teaching and learning at school. Although specialists in education and teaching first became

interested in the impact of classroom discourse and interaction on students' learning and the development of cognitive skills in the 1930s and 1940s, since that time, research on classroom talk has moved forward in a number of directions. In the study of language and applied linguistics, classroom talk has been the subject of considerable exploration in discourse, conversation, and text analyses, as well as sociolinguistic and sociocultural features of interaction.

The linguistic features of classroom talk were studied intensively in the 1970s and 1980s, when the uses of language and forms of interaction at school became an important venue in discourse, pragmatic, and literacy studies. Many of the early discourse analyses focused on the linguistic features of talk, narrative structure, common speech acts, their sequences, and the contexts in which they occurred, as well as the flow of classroom speech (e.g., Sinclair and Coulthard, 1975; Stubbs, 1983). As a matter of course, these studies approached classroom talk as

occurrences of conversational discourse, without attempting to discern the effect of the language spoken in the classroom on student learning and the educational processes. The analyses of the discourse flow and the language of interaction revealed that classroom talk is highly structured and routinized.

Building on the discourse-analytic foundation, the influential work of such sociolinguists and cognitive linguists as Cazden (2001), Gumperz (1982, 1986), Edwards and Mercer (1987), and Edwards and Westgate (1994) employed a combination of methodological perspectives in their explorations of the spoken discourse, language, and the structure of interaction in schooling. In general terms, sociolinguistics takes into account the social contexts and the structure of interaction to determine how they shape the spoken language. Sociolinguistic research methods in the classroom are usually complemented by ethnographic and pragmatic perspectives. Taken together, the findings of these studies have brought to the foreground issues of power, socioeconomic class, culture, and the social construction of experience in the classroom. Many, if not most, of these investigations point to the common and frequent mismatches between the normative properties of the school language and the language used in students' families.

A number of important and congruent findings have emerged from the study of classroom discourse and spoken language. One prominent thread in research is that a large majority of classroom interactions occur between the teacher and the students, individually or in groups, although some student-student interactions also take place during group or collaborative activities. Investigations carried out in different locations and countries around the world have shown that in classroom interactions, teachers talk approximately 75% of the time, with the remainder divided among the students. This pattern of talk seems to be comparatively consistent and, on the whole, resistant to change, despite the calls for its modification or attempted educational reforms (e.g., van Lier, 1988, 1996; Dysthe, 1996; Nystrand, 1997).

Another strand that runs through practically all studies is that classroom talk includes a number of predictable and observable sequences. Much of the classroom spoken language centers around knowledge and information elicitation turns between the teacher and the students, cohesive topical stretches of talk, or exchanges motivated by instructional activity in the classroom. In general terms, teacher-student exchanges reflect the unequal and hierarchical relationship of their participants in teacher-fronted classrooms (Edwards and Westgate, 1994).

The typical conversational patterns in such dyadic exchanges proceed along the lines of what

has become known as Initiation-Response-Feedback (IRF) (also called Initiation-Response-Evaluation or Question-Answer-Comment), e.g.:

Teacher: So, why did Peter run to the village?

Student: For a joke.

Teacher: Right!

In such routine classroom sequences, the teacher initiates the interaction or asks a question, the student responds or answers the question, and the teacher takes the concluding turn that provides a commentary (e.g., *So, Peter was bored*) or an evaluation (e.g., *Good/Great answer*).

Spoken language in the classroom is fundamentally different from many other types of talk, such as conversations among peers, coworkers, or family members. Some researchers, such as, for example, Mehan (1979) and van Lier (1996), have pointed out that IRF interactions are, by their nature, artificial and constrained and, for this reason, they cannot be analyzed as ordinary conversational discourse that follows ordinary interactional conventions. In their view, the institutionalized structure of classroom talk is crucially distinct when the teacher nominates topics and speakers, and controls turn-taking and the amount of participant talk.

The decades of investigating talk in the classroom have also identified the social, cultural, and behavioral practices that predominate in classroom discourse. Numerous studies carried out in such locations as the United States, the United Kingdom, and Scandinavia have demonstrated that complex systems of socio-cultural prescriptions and expectations that exist in the wider society are strongly reflected in the norms of speaking and behaving in the classroom. Influential works by, for example, Heath (1983) and Gee (1990), highlight the pervasive discontinuities between the middle-class linguistic and interactional practices widely adopted in schooling and those in children's homes. The disparities between the rigidly prescribed and traditional rules of the classroom talk extend to the learning, socialization, and literacy development of the children in racially and linguistically diverse schools. Examples of language and interaction mismatches abound (e.g., Scollon and Scollon, 1981; Brock *et al.*, 1998):

- Spanish-speaking students in the United States are not always familiar with the predominant norms of classroom behavior when students are expected to be quiet while the teacher or another student is speaking.
- Native American students often participate in class conversations collectively, but not individually, as is usually expected in U.S. and Canadian schools.

- Ethnic Chinese students in U.K. and Australian schools rarely speak during requisite classroom activities and strongly prefer to work alone instead of working in groups, where much conversation is required.

In all, a large number of sociolinguistic and ethnographic studies have shown conclusively that the practice of classroom talk and the rigid norms of interaction in schooling represent culturally bound contexts for learning. As an outcome, the learning and literacy development of racial and linguistic minority students can be constrained in the classrooms where the structure of talk and discourse follows sociocultural prescriptions different from those in the students' communities outside the school.

From a different vantage point, research in discourse and conversation analysis, as well as language acquisition, has also shown that classroom talk has numerous important learning, cognitive, and social functions. The most common of these include exposure to language and linguistic input in the form of, for example, direct instruction, questions and answers, orientations to topics, information elicitations, explanations, hypothesis-making, and using evidence. In the following example of a story-circle discussion, the teacher attempts to elicit more elaborate explanations and evidential support for the students' in effect accurate appraisal of the story events:

Teacher: Ok, so Laura got a pretty new dress.... A very nice dress. She must have liked it. So, did she like it?

Several students together: Noooooooo.

Teacher: She didn't? Well, no, she didn't.... Eh, ok, ... so how do we know that she didn't?

Sam: She said ... I ... I don't need it ... it ... the new one. So, she didn't.

Teacher: Good job, Sam, good thinking.... Laura *really* didn't need this dress? Ok, or maybe, she didn't like it? Can we tell? How can we tell?

In addition to guiding the students to support their conclusion by means of the information in the story, the teacher also uses relatively advanced syntactic constructions, such as *must have liked it* and a number of complex sentences with noun clauses and negation.

More recently, with the increased understanding of learners' cognitive and linguistic development, investigations of classroom talk have continued to gain importance in language teaching and education of second language and minority students. In many cases, discourse and conversation analyses of classroom talk have also shown that language uses and interactions in educational contexts play an important role in learner language and cognitive development (see, e.g., Edwards and Westgate, 1994; Dysthe, 1996; Seedhouse, 2004). For instance, the uses of lexical and grammatical features in classroom talk

have allowed researchers to assess the value of classroom language exposure and input in language learning and the growth of first and second language literacy skills.

Among other venues, for example, the uses of display and referential questions in classroom talk have been extensively researched. The purpose of display questions is to elicit information already known to the interaction participant, who asks the question to lead to the display of knowledge or familiarity with information, e.g., "What do we call this thing?" On the other hand, referential questions elicit information that is not known to the speaker, e.g., "Why did you and Mary put this picture before that one?" Studies of referential questions have shown that their educational uses lead to different classroom exchanges that result in significantly longer speech events, higher rates of lexically and syntactically complex responses, and greater opportunities for learner language use (e.g., Edwards and Mercer, 1987; van Lier, 1996).

In-depth investigations of classroom talk have undertaken to gain insight into a large number of sociocultural and linguistic properties of interaction, such as equal and unequal power relationships, some aspects of turn-taking, talk management, and the timing and length of speech events (e.g., Markee, 2000). From the perspective of conversation analysis, classroom interactions have provided a fertile ground for examinations of repair, correction, self-correction, discourse, and face-saving markers in equal and unequal power educational contexts.

At present, sociologists, educators, and linguists almost universally recognize that social and cultural institutions of schooling are inseparable from how language and discourse are employed to transmit knowledge and socialize learners (e.g., Watson-Gegeo, 1997; Cazden, 2001).

Code Switching

S Gross, East Tennessee State University, Johnson City, TN, USA

© 2006 Elsevier Ltd. All rights reserved.

In many bi- and multilingual communities around the world, speakers need to choose, often at an unconscious level, which language to use in their interactions with other members of the community. One of the choices that bilingual speakers often make is to code-switch: that is, speakers switch back and forth between languages (or varieties of the same language), sometimes within the same utterance (see **Bilingualism**).

The motivations for code switching have often been treated simply as lists of possible functions for code switching. For example, Appel and Muysken (1987) cite five such functions. First, code switching may serve a referential function by compensating for the speaker's lack of knowledge in one language, perhaps on a certain subject. Second, it may serve a directive function by including or excluding the listener. Third, code switching may have an expressive function by identifying the speaker as someone having a mixed cultural identity. Fourth, it may have a phatic function indicating a change in tone in the conversation. And fifth, it may serve a metalinguistic function when code switching is used to comment on the languages involved.

While such lists are useful places to start, and no one would deny that code switching can certainly serve these functions, these types of lists fail to answer the question of what motivates speakers to make the choices they do at a particular point in a conversation. This article reviews the major proposals that have been advanced regarding the following question: why do speakers choose to engage in code switching in the first place?

Code Switching as a Research Topic

The current interest in code switching can be dated to a 1972 study of language use in Hemnesberget, a small village in northern Norway, conducted by Jan Blom and John Gumperz and described in a volume on sociolinguistics edited by Gumperz and Hymes (1972). In Hemnesberget, two varieties of Norwegian are used: Ranamål, a local dialect, and Bokmål, the standard variety. However, speakers' decisions regarding which variety to use are by no means arbitrary or haphazard. In general, Ranamål, the local variety, is used in local activities and relationships, reflecting shared identities with the local culture. In contrast, Bokmål is used in official settings such as school, church, and the media, communicating an individual's dissociation from the local group, i.e., not stressing his or her local ties.

Blom and Gumperz distinguish between two main functions of code switching: situational and

metaphorical. In situational code switching, which seems to be similar to the notion of diglossia, the speaker's choice of language is constrained by factors external to her/his own motivations, for example, the status of the interlocutor, the setting of the conversation, or the topic of conversation. So, in Hemnesberget, Blom and Gumperz observed that when an outsider joins a group of locals engaged in a conversation, the locals will often switch from the local variety, Ranamål, to the standard variety, Bokmål. In a later work, Gumperz (1982) introduces the distinction between 'we' and 'they' codes, which further amplifies the kind of linguistic alternation that occurs in situational code switching. 'We' codes are associated with home and family, while 'they' codes are associated with public discourse. In contrast to situational code switching, speakers may engage in a more complex type of code switching to create a 'metaphoric' effect. In his 1982 book, Gumperz explains that this metaphoric effect is a way for speakers to communicate "information about how they intend their words to be understood" (1982: 61). The classic example of metaphorical code switching from the Blom and Gumperz 1972 article is from a conversation at the local community administration office, where two villagers switch from the standard variety of Norwegian, in which they had been discussing official business, to the local variety to discuss family and other private affairs.

The Blom and Gumperz study is important because it illustrates that code switching is a complex, skilled linguistic strategy used by bilinguals to convey important social meanings above and beyond the referential content of an utterance. However, this is not to say that the Blom and Gumperz article has not generated some criticism over the years. In addition to some overlap and lack of clarity in the definitions of situational versus metaphorical switching, this model of code switching implies a sharp boundary between the two types of switching. In fact, Myers-Scotton (1993: 55) argues that the metaphorical meaning of a switched utterance is derived from its situationally based meaning. In any case, it is fair to say that this Blom and Gumperz study sparked an interest in studying code switching data in terms of a dynamic, interactional model that focuses on individual choices rather than static factors related to an individual's social status (see **Social Class and Status**).

The Audience-Centered Approach to Code Switching

Using a social psychological theory of language use, Howard Giles and his associates have developed a model of interpersonal communication that considers

how speakers change the way they speak according to their audience. Giles refers to this type of strategy as accommodation (see **Speech Accommodation Theory and Audience Design**). Within Giles's speech accommodation theory, speakers are motivated by their desire for approval *vis-à-vis* their desire to dissociate themselves from the hearer. These concerns are cognitively salient and are realized by speech convergence (similar styles of speaking) or divergence (different styles of speaking). In fact, Giles predicted from these assumptions that the greater the effort in converging, the more favorably the individual will be evaluated by the listener. Thus, convergence and divergence are linguistic strategies to either decrease or increase social distance between participants in a conversation.

Although the premises behind speech accommodation theory have not been rigorously tested using code switching data in any comprehensive way, it is not difficult to see how the model could be used to explain speakers' motivations for code switching. For example, to test the prediction regarding how listeners will evaluate a speaker based on the speaker's perceived effort at converging, Giles *et al.* (1973) conducted an experiment involving bilingual English Canadian students who were asked to rate their reactions to a set of taped descriptions of a simple harbor scene given by bilingual French Canadian students. Different versions of this description – reflecting different levels of linguistic convergence to monolingual English – were presented to the English Canadian raters. The results of this experiment supported the prediction that the greater the effort in converging, the more favorably the speaker would be perceived. More specifically, the most convergent bilingual French Canadian student was viewed as the most considerate and the most concerned about bridging the cultural gap between French and English Canadians.

Speech accommodation theory has been successfully applied mainly in the contexts of dialect or style switching. However, the theory and its predictions still await further testing on code switching in bilingual settings.

The Conversation Analytic Approach to Code Switching

Both the Gumperz and the Giles models of code switching attend to extralinguistic factors such as topic, setting, and participants as influencing speakers' linguistic choices in conversations. Peter Auer (1984) questioned these assumptions and specifically questioned the way 'situation' was defined. For Auer, situation was not a static set of contextual features that constrain linguistic choices. Rather, situation was seen as a dynamic phenomenon, emerging from

the sequential nature of a conversational interaction. Using the terminology and the techniques of ethnomethodology and conversation analysis, Auer argued that the meaning behind code switching must be interpreted on the basis of the linguistic choices made by the participants themselves in the preceding and following turns in a conversation. In other words, for Auer, social meaning is constituted locally rather than at a societal level (*see Conversation Analysis*).

Studies that use the technique of conversation analysis typically assign no independent semantic value to either of the languages involved. Instead, the conversational meaning of code switching results from the mere juxtaposition of the two languages, which generates contextualization cues whereby participants signal various contextual presuppositions. Thus, this language switching has a value of its own, independent of the direction of code alternation.

Some have argued that an approach that focuses on the negotiation of meaning as locally constructed cannot generalize across interactions in order to build explanatory theories. However, Auer (1995) has identified several basic code switching patterns that correspond to identifiable meanings, such as participant-related alternations, which reflect language competence or preference on the part of the speaker, and discourse-related alternations, which signal, for example, topic change (among other functions). Nevertheless, most researchers still recognize that in multilingual communities, each language available in the community indexes specific social and interactional meanings, and listeners tend to attribute consistent interpretations to the particular language choices that speakers make (*see Pragmatic Indexing*).

The Marked Model: A Speaker-Centered Approach to Code Switching

One of the more richly developed models designed to explain the sociopragmatic motivations for code switching is Carol Myers-Scotton's markedness model, which developed out of her field research in East Africa. The central premise of the markedness model is that speakers are rational actors who make code selections in such a way as to minimize costs and maximize rewards; that is, speakers are concerned with optimizing the outcomes of an interaction in their own favor.

This notion of the speaker as a rational actor making certain decisions about code choice, albeit at a largely unconscious level, is also evident in speech accommodation theory as well as in Gumperz's approach to code switching. However, unlike these other models, which consign the primary motivation for code switching to the addressee or to some

other factor external to the speaker (e.g., topic or social setting), the markedness model is primarily a speaker-centered approach to communication.

Markedness and Communicative Competence

Within the marked model, all code choices fall along a continuum, as more or less marked or unmarked. With respect to bilingual speech, the unmarked choice simply refers to the linguistic variety that is expected, given the societal norms for that interaction. In contrast, marked choices fall at the other end of this continuum; that is, they are in some sense unusual or unexpected for the particular social interaction.

Furthermore, all speakers possess what Myers-Scotton calls a markedness evaluator, or the capacity to evaluate linguistic choices in terms of markedness, as part of their innate communicative competence (*see Communicative Competence*). While the capacity to assign markedness readings to linguistic choices is innate, the markedness continuum is established through exposure to the range of linguistic options used in the community.

Explaining Speakers' Choices

All code choices can ultimately be explained in terms of speakers' motivations to optimize the outcomes of the interaction. Most choices that speakers make affirm the norms that are in place for the particular exchange. These are unmarked choices, and they are usually the safest choices to make. The particular code used by the speaker is important only insofar as the participants view its status as marked or unmarked for that type of interaction. Thus, in a multilingual setting such as Nairobi, Kenya, the unmarked choice for most business transactions between strangers is Swahili. However, if the participants discover during the course of their conversation that they are members of the Luyia ethnic group, they will often switch into Luyia to continue the conversation. Luyia, then, becomes the unmarked choice, given the ethnic identity of the participants. However, code switching between Swahili and English within the same turn, within the same sentence, and even within words is typically the unmarked choice for informal social gatherings between educated, middle-class peers in Nairobi. Hence, the markedness of linguistic choices must be evaluated in terms of the norms for a particular exchange; the unmarked setting may even change within a conversation.

In contrast to the relative safety of unmarked choices, marked choices carry with them some element of risk for someone who wishes to defy the norms. Importantly, the interpretation that a marked choice receives derives from its contrast with the

unmarked choice for that exchange. That is, the unexpectedness, the 'otherness' of a marked choice carries significant social meaning. Marked choices are typically used to redefine the relationship between the speaker and the addressee, often as an expression of the speaker's authority or power, to indicate anger, or to assert one's ethnic identity (see **Identity and Language; Power and Pragmatics**). All these strategies can be subsumed under a single general principle: speakers make marked choices to negotiate a change in the expected social distance between the participants, either increasing or decreasing it.

The Significance of the Markedness Model

Since its formulation, the markedness model has been successfully used to explain code switching between languages, between dialects and registers, and even between stylistic choices in literary contexts. The strength of the markedness model is its ability to explain not only unmarked choices, which other models do as well, but also its ability to explain marked choices. Furthermore, the markedness model addresses the universal aspects of communicative competence in terms of the cognitive abilities that use readings of markedness to assess speakers' intentions. For these reasons, the markedness model is a powerful tool not only for code switching research, but also for any examination of the ways in which speakers use language to achieve interactional goals.

Codes, Elaborated and Restricted

A Capone, Barcellona, Italy

Bernstein was among the first scholars to focus on the correlation between the scholastic success (or failure) of a learner and the social class he or she belonged to. A student living in a well-off family, having many

cultural stimuli (books, newspapers, periodicals, films, etc.) is bound to develop a rich and fully articulated language (a so-called 'elaborate code'), whereas a student who belongs to a working-class family and is exposed to poor linguistic and cultural stimuli, develops a fragmented, poor, syntactically deficient language (called a 'restricted code' by Bernstein) (see Bernstein, 1971–1975).

Regarding the Chomskyan theory that language naturally develops in the brain, due to the interaction of biologically innate structures and the environment to which the child is exposed, it may be the case that the data to which the child is exposed are so poor and confused that it is easy to demonstrate that the innate learning program prevails over the environmental stimuli, Bernstein therefore emphasizes the predominant role played by the environment in shaping the learning process. Of course, the correlation between social class is not, strictly speaking, without exceptions, because much of the learning process depends on the lifestyle of the family under consideration. There are exceptional working-class families where parents, contrary to all expectations, have good knowledge of the language and place great importance on culture, but the norm is that, within working-class families, cultural stimuli are less predominant than in more well-off families.

The problem, for sociologists, is how to offset the disadvantages of the pupils belonging to working-class families and how pedagogues (and teachers) can counteract such deterministic effects in the case of these children.

A possible solution to the problem is to ensure that the school (or the class) becomes another miniature family and that the negative effects of the families are compensated for by the pedagogical action of the school. The school should, therefore, be a positive environment in which pupils are exposed to positive cultural and affective stimuli that help their personalities grow and come to maturity. In such a model of the school, teachers lose their primary function of

being transmitters of notions (knowledge, in general) and are required to take the roles of educators or pedagogues who act as models and provisionally replace (at least within the boundaries of the school) the family by setting good examples for the students, and, in particular, exposing them to the positive aspects of culture, intended as knowledge that interacts with the individual to make him or her grow up intellectually and emotionally. To compensate for the negative effects of families, in which dialogue and conversation have died or are confined to adjacency pairs of questions/answers or orders/replies, teachers have to play the role of communicators and stimulate communication. It is, in my view, impossible for a student to make progress in his or her language (to develop a more articulated written or oral mode of expression) unless he or she understands the function of communication, which is that of transmitting knowledge, but also of enhancing the expressive as well as the interpersonal function. To communicate is not only to express propositions (concerning others), but also to express propositions concerning what we really are and feel, and, by so doing, to interact with others, creating an intersubjective dimension in which social life is possible (see Capone, 2003).

Cognitive Pragmatics

F M Bosco, University of Torino, Torino, Italy

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Cognitive pragmatics is concerned with the mental processes involved in intentional communication. Typically, studies within this area focus on cognitive processes underlying the comprehension of a linguistic speech act and overlook linguistic production or extralinguistic communication.

As far as cognitive processes are concerned authors in this field are interested in both the inferential chains necessary to understand a communicator's intention starting from the utterance he proffered and

the different mental representations underlying the comprehension of various communicative phenomena as cognitive processes. Thus, a theory in cognitive pragmatics aims to explain what mental processes a person actually engages in during a communicative interaction (see **Shared Knowledge**).

Relevance theory (Sperber and Wilson, 1986/1995) is usually identified as the principal theoretical framework in the area of cognitive pragmatics (see **Relevance Theory**). Nonetheless, in the last decade, other theories have been developed. These include a far-reaching theory of the cognitive processes underlying human communication, known as the Cognitive Pragmatics theory (Airenti *et al.*, 1993a, 1993b; Bara, 2005), and the Graded Salience Hypothesis (Giora, 2003), a theory which focuses

on mental inferences underlying the comprehension of literal vs. figurative language (see **Metaphor: Psychological Aspects; Accessibility Theory**).

Describing the cognitive processes involved in communicative interaction is interesting not only for the study of such processes as fixed states – an approach that takes into consideration exclusively the final stage in healthy adult subjects – but also for the consideration of how a given function develops from infancy, through childhood, and to adulthood, and how it eventually decays in subjects with brain injuries (Bara, 1995). Such an approach makes it possible to better comprehend, from a cognitive perspective, how pragmatic competence develops and what neurocognitive structures might cause deficits in people's performance if damaged.

A closely related topic is the identification of the cognitive components that contribute to the realization of a complete pragmatic competence. From this perspective, it is important to consider the role played by a person's Theory of Mind and by the Executive Function (see below) during a communicative interaction.

Cognitive Pragmatics Theory

Airenti *et al.* (1993a, 1993b) presented a theory of the cognitive processes underlying human communication aiming to provide a unified theoretical framework for the explanation of different communicative phenomena (Bara, 2005). The authors proposed that their theoretical analysis holds for both linguistic and extralinguistic communication, and thus introduced, with reference to the interlocutors, the terms 'actor' and 'partner' instead of the classical 'speaker' and 'hearer.' The theory assumes that the literal meaning of an utterance is necessary but not sufficient to the partner in order for him or her to reconstruct the meaning conveyed by the actor, and that in order to understand the actor's communicative intention, the partner has to recognize a 'behavior game' the actor is proposing for him (the partner) to play. The behavior game is a social structure mutually shared by the participants of the communicative interaction. Suppose, for example, that while you are working in your office, a colleague walks in and says: [1] *It's snowing outside*. Although the literal meaning of the utterance is completely clear, you probably are utterly bewildered about how to respond. Only if [1] is understood as an invitation not to go outside, a request to close the window, a proposal to go skiing next week-end (that is, only if, in some way, the reason or reasons for uttering the expression were evident), will you be able to make the necessary inferences and answer appropriately. The utterance, pure and

simple, without a game to refer to, has in itself no communicative significance whatsoever. Thus, an utterance extrapolated from its context of reference has no communicative meaning and cannot have any communicative effect on the partner.

Starting from the assumption that the communicative meaning of an utterance is intrinsically linked to the context within which it is proffered, Bosco *et al.* (2004a) defined a taxonomy of six categories of context: Access, Space, Time, Discourse, Behavioral Move, and Status. Using contextual information, the partner can identify the behavior game bid by the speaker, which allows him to fully comprehend the actor communicative intention.

Following the tenets of the Cognitive Pragmatics theory, Bucciarelli *et al.* (2003) proposed that two cognitive factors affect comprehension of various kind of pragmatic phenomena: the 'inferential load' and the 'complexity of mental representations' underlying the comprehension of a communicative act.

Inferential Load: Simple and Complex Speech Acts

Searle (1975) claimed that in speech act comprehension, the literal interpretation of an utterance always has priority with respect to any other interpretations derived from it. According to Searle, understanding an indirect speech act, e.g., [2] *Would you mind passing me the salt?*, is harder than understanding a direct speech act, e.g., [3] *Please pass me the salt*, because it requires a longer inferential process.

Bara and Bucciarelli (1998) provided empirical evidence that, beginning at two-and-a-half years of age, children find direct speech acts such as [4] *Please sit down*, and conventional indirects such as [5] *Would you mind closing the door?* equally easy to comprehend. In a further study, Bucciarelli *et al.* (2003) found that starting at age two-and-a-half years, children find both direct and conventional indirect speech acts easier to understand than nonconventional indirect speech acts, such as the utterance [6] *Excuse me, I'm studying* when it is a request to a partner who is hammering in a nail to stop making noise.

Using the tenets of Cognitive Pragmatics theory, it is possible to abandon the distinction between direct and indirect speech acts and adopt a new one based on the difference between inferential processes involved in comprehending simple as against complex communicative acts (Bara and Bucciarelli, 1998). According to the theory, the partner's understanding of any kind of speech act depends on the comprehension of the behavioral game bid by the actor; an agent will interpret an interlocutor's utterance based on the grounds that are assumed to be shared. In this perspective, the partner's difficulty in understanding a

communicative act depends on the inferential chain necessary to refer the utterance to the game intended by the actor. Direct and conventional indirect speech acts make immediate reference to the game, and thus are defined as 'simple speech acts.' On the other hand, nonconventional indirect speech acts can be referred to as 'complex speech acts,' because they require a chain of inferential steps due to the fact that the specific behavior game of which they are a move is not immediately identifiable. For example, to understand [4] and [5], it is sufficient for the partner to refer to the 'Ask for Something' game. In order to understand [6], a more complex inferential process is necessary: the partner needs to share with the actor the belief that when a person is studying, he needs silence and that since hammering is noisy [6] is a request to stop it is noisy. Only then, the partner can attribute to the utterance the value of a move in the 'Ask for Something' game. Thus, if the problem is how to access the game, the distinction between direct and indirect speech acts is not relevant. It is the complexity of the inferential steps necessary to refer the utterance to the game bid by the actor that accounts for the difficulties in speech act comprehension.

This distinction applies not only to standard communicative acts such as direct, conventional indirect, and nonconventional indirect speech acts, but also to nonstandard ones (such as ironic and deceitful) ones (Bara *et al.*, 1999a). The same distinction between simple and complex standard, ironic, and deceitful communicative acts holds for extralinguistic communication acts as well (see **Irony**). That is, the distinction holds also when the actor communicates with the partner only through gestures (Bosco *et al.*, 2004b) (see **Gestures, Pragmatic Aspects**).

The inferential load underlying a communicative act may explain the difference in difficulty that exists in the comprehension of different communicative acts pertaining to the same pragmatic category, such as between simple and complex standard communicative acts. To explain the difference in difficulty that might occur among communicative acts pertaining to a different pragmatic category, such as between a direct communicative act and a deceitful communicative act, is necessary to consider the complexity of the mental representations involved in their comprehension.

Complexity of Mental Representations

Still within the framework of Cognitive Pragmatics theory and along with the same complexity of the inferential load involved, Bucciarelli *et al.* (2003) described an increasing difficulty in comprehending simple communicative acts of different sorts: simple

standard, simple deceitful, and simple ironic communicative acts.

According to the theory, in standard communication, default rules of inference are used to understand another person's mental states; default rules are always valid unless their consequences are explicitly denied. Indeed, in standard communication, what the actor says is in line with his private beliefs. Direct, conventional indirect, and nonconventional indirect speech acts are all examples of standard communication. In terms of mental representations, to comprehend a standard communicative act, the partner has to simply refer the utterance proffered by the actor to the behavior game he bids.

On the other hand, nonstandard communication such as irony and deceit involves the comprehension of communicative acts *via* the blocking of default rules and the occurrence of more complex inferential processes that involve conflicts between the beliefs the actor has shared with the partner and the latter's private beliefs. In the comprehension of irony and deceit, the mental representations involved produce a difference between what the actor communicates and what he privately entertains. It follows that, along with the same complexity of the inferential load involved, standard communicative acts are easier to deal with than nonstandard pragmatic phenomena.

According to Bucciarelli *et al.* (2003), in the case of the comprehension of deceit, the partner has to recognize the difference between the mental states that are expressed and those the actor privately entertains. Consider for instance the following example: Mark and Ann share that the lecture they just attended was incredibly boring. Later Ann meets John and tells him that Mark and she attended a tedious lecture. In the afternoon also Mark meets John, who asks him about the lecture. Actually, Mark is annoyed with John because John did not go to the lecture and he does not want John to know that he feels he wasted the whole morning. Mark does not know that John has already met Ann, thus he answers: [7] *It was really interesting!* John can understand that Mark is trying to deceive him because he recognizes the difference between the mental state that Mark is expressing and the one that he truly and privately entertains.

A statement, instead, becomes ironic when, in addition to the awareness of this difference, the partner also recognizes that the mental states expressed contrast with the scenario that he shares with the actor. For example, some months later, during a chat with Mark, Ann asks: *Do you remember the lecture that we attended some months ago?* Mark answers: [8] *It was really interesting!* What makes this utterance ironic is the fact that both interlocutors share that

the lecture had actually been boring. Thus, the difference between irony and deceit lies not in the partner's awareness of the difference between the mental states that the actor expressed and those that he actually entertains, but in his awareness that he does or does not share this difference with the actor.

In the case of irony, the partner has to represent not only the discrepancy between the mental states that the actor expressed and those that he privately entertains, but also that such awareness is shared with the actor. This makes an ironic communicative act more difficult to comprehend than a deceitful one.

Bucciarelli *et al.* (2003) showed the existence of an increase in difficulty in the comprehension of simple standard communicative acts, simple deceptions, and simple ironies with an experiment carried out on children from two-and-a-half to seven years of age. The authors also pointed out that the same children show a similar predicted gradation of difficulty in understanding the same pragmatic phenomena, both when these are expressed by linguistic speech acts and when these are expressed by communicative gestures. Regardless of the communicative channel used by the actor, linguistic or extralinguistic, children find simple standard speech acts easier to comprehend than simple deceptions, which are, in turn, easier to comprehend than simple ironic communicative acts.

Finally, an overall consideration of the mentioned results makes it possible to conclude that all of the theoretical predictions (both derived from the Cognitive Pragmatics theory and grounded on a person's cognitive processes underlying the communicative comprehension) hold true for the same pragmatic phenomena whether expressed by linguistic speech acts or by gestures. These results seem to indicate that linguistic and extralinguistic communicative acts share the most relevant mental processes in each of the specific pragmatic phenomena investigated and suggest that pragmatic competence shares the same cognitive faculty – regardless of the input processed – be it linguistic or extralinguistic. It is possible to interpret such empirical evidence as being in favor of a unified theoretical framework of human communication in which linguistic and extralinguistic communication develop in parallel being different aspects of a unique communicative competence (see Bara and Tirassa, 1999; Bara, 2005) (*see Communicative Principle and Communication*).

Cognitive Pragmatics and Development

In this section, we shall examine the empirical evidence in favor of the existence of cognitive processes of increasing complexity that underlie different pragmatic phenomena. The developmental domain is particularly interesting for this aim because it makes it

possible to observe errors in the comprehension of different kinds of pragmatics tasks that allow us to falsify our hypotheses regarding the complexity of the mental processes involved in specific phenomena. However, adult subjects possess a fully developed cognitive system and communicative competence, and thus they do not show any interesting errors in comprehending or producing different kinds of communicative acts; it is only possible to analyze their time of reaction in solving such tasks.

On the other hand, if inferential processes and mental representations of increasing complexity underlie the comprehension of various kind of pragmatic phenomena, then it is possible to explain why, during the development of children's communicative competence, some communicative acts are understood and produced before others are. For example, children initially only understand sincere communicative acts and only later on in their development do they start comprehending, for example, deception and irony. Children's ability to deal with mental representations and inferential chains of increasing complexity develops with age, and this fact helps explain the development of their pragmatic competence.

From this perspective, the increasing capacity to construct and manipulate complex mental representations is involved in the emergence of preschoolers' and kindergarten student's capacity to deceive. A deceptive task could be made easier to comprehend by reducing the number of characters, episodes, and scenes involved in the task, and by including a deceptive context (Sullivan *et al.*, 1994).

Likewise the ability to comprehend and produce different forms of ironies involves an increasing and sophisticated inferential ability. Lucariello and Mindolovich (1995) carried out a study on the ability of 6- and 8-year-old children to provide ironic endings to unfinished stories. The authors claimed that the recognition and the construction of (situational) ironic events involve the ability to manipulate the representations of events. These representations have to be critically viewed, and disassembled in order to create new, different, and ironic event structures. Also, different forms of irony behave in different ways, as the authors' experiments show. Their results show that older children construct more complex ironic derivations from the representational base than younger children do.

Just as it is possible to better understand the development of pragmatic competence by considering the cognitive processes involved in a specific communicative act, it also is possible to explain deficits in performance in cases of brain damage. The ability of children with closed head injury to solve pragmatic tasks is specifically impaired (for a review, see Bara *et al.*, 1999b). These subjects performed worse than

did their normal peers in specific pragmatic tasks such as bridging the inferential gap between events in stereotypical social situations and tasks such as comprehending utterances that require inferential processes because of their use of idiomatic and figurative language (Dennis and Barnes, 1990).

Cognitive Pragmatics and Brain Damage

Neuropsychological diseases affect communicative performance in various ways, depending on which relevant cognitive subsystem is damaged. The information obtained by studying these abnormal processes provides us with an opportunity to better understand the architecture of the brain/mind and its relationship to pragmatic competence (Tirassa, 1999; Bara and Tirassa, 2000). Acquired brain damage impairs certain cognitive processes while leaving others unaffected. For example, it is well-documented in the literature that aphasic patients with left-brain damage have residual pragmatic competence despite their language impairment.

On the other hand, what different cerebral injuries have in common is a damaged capacity to deal with phenomena that require complex mental processes in order to be understood. In particular, if the tasks require more complex inferences, then this capacity seems to be more damaged than in other cases, as we will show later in this section. Results like these seem to confirm the assumption that different pragmatic phenomena require the activation of increasingly complex cognitive processes.

McDonald and Pearce (1996) found that traumatic brain injured patients (TBI) do not have difficulty in the comprehension of written sincere exchanges such as [9] Mark: *What a great football game!*; Wayne: *So you are glad I asked you?*, but they have several problems, compared to the normal control subjects, in comprehending ironic exchanges such as [10] Mark: *What a great football game!*; Wayne: *Sorry I made you come*. The authors gave the subjects the same experimental material in auditory form and found that the patients' performance did not improve. The authors concluded that TBI patients have difficulty in comprehending irony and that, even if the tone of voice usually facilitates the comprehension of ironic remarks, it is not sufficient on its own.

Furthermore, McDonald (1999) found that, surprisingly, TBI patients have no problem understanding written ironic utterances such as [11] Tom: *That's a big dog*; Monica: *Yes, it's a miniature poodle*. The author suggested that [11] might require a shorter inferential chain compared to [10] in order to be understood. Indeed, in comprehending [11], it is sufficient to understand what Monica answers as meaning that Tom's statement meant the opposite of what

it said. In [10], however, Wayne's response is not only a rejection of the original comment, but an allusion to Mark's actual reaction to the game. Thus, there were at least two necessary inferential steps in the comprehension process. Such findings are in line with the proposal that different kinds of irony may vary in their difficulty of being understood, according to the complexity of the required inferential load (Bara *et al.*, 1999a).

Particularly interesting from our perspective are studies that showed that the decay of pragmatic competence in closed head injured subjects (CHI) reflects the same type of development that is observed in normal children, i.e., the capacities acquired later in the development of the pragmatic ability are the most damaged. Using a linguistic experimental protocol, Bara *et al.* (1997) tested a group of CHI subjects and found that specific pragmatic tasks such as the comprehension of nonstandard communication, e.g., deceit and irony, are more difficult than tasks requiring only simple mental representations, such as the comprehension of standard communication involving only direct, conventional, and nonconventional indirect speech acts. In addition, the authors found no differences in patients' comprehension of direct and conventional indirect speech acts. The same results were observed in the performance of children aged 2 to 6 years old who were tested by the same experimental protocol (Bara and Bucciarelli, 1998). It should also be noted that Bara *et al.* (1997) presented two classical tests on false belief to CHI patients in order to measure their theory of mind, but did not find any significant difference with the control group of children who were not brain damaged. Thus, the patients' poor performance on pragmatic tasks cannot be ascribed to a deficit of the Theory of Mind; that is, their poor performance cannot be ascribed to an inability to understand another person's mental states.

Moreover, Bara *et al.* (2000) used a similar extralinguistic version of the same pragmatic experimental protocol and evaluated the comprehension of standard communication, i.e., simple and complex communicative acts, and nonstandard communication, i.e., deceit and irony. Such a protocol contains videotaped scenes wherein the pragmatic phenomena are presented using extralinguistic means, such as pointing or clapping. The subjects were firstly a group of children 2–6 years of age and secondly a group of Alzheimer's disease patients, and found that children show the same tendency in the development of extralinguistic competence that was observed by Bara and Bucciarelli (1998) in the linguistic domain. In addition, the authors observed a similar tendency toward decay in the Alzheimer's patients' extralinguistic competence: the nonstandard extralinguistic tasks

are understood less well than are the standard communicative tasks. Finally, the trend of decaying pragmatic competence in the Alzheimer patient group matched the results obtained by CHI patients, when tested according to the same extralinguistic protocol (Bara *et al.*, 2001). The CHI subjects were also given several neuropsychological tests, but no statistical correlation between the subjects' performance on the pragmatic protocol and their performance on these collateral neuropsychological tests was found. Thus, the patient's poor performance cannot be ascribed to a deficit in their executive functioning.

As already observed for the development of pragmatic linguistic and extralinguistic competence, the empirical data concerning brain damaged subjects seem to be in favor of the existence of a unified pragmatic competence which is independent of the input – whether it is linguistic or extralinguistic. That is, the comprehension of speech acts and extralinguistic communicative acts shares the most relevant mental processes when tested on different pragmatic phenomena, and the pragmatic competence seems to be independent of the expressive means used to realize it.

Cognitive Pragmatics and the Executive Function

While the literature provides empirical evidence that mental processes involved in various pragmatic tasks can be ordered according to increasing difficulty, as we have seen above, in order fully comprehend pragmatic competence from a cognitive perspective, we need to consider also a further factor affecting the human ability to communicate: the executive functions.

The Executive Function is a cognitive construct used to describe the goal-directed behaviors that are mediated by the frontal lobes. The Executive Function guides a person's actions and enables him to behave adaptively and flexibly; it includes cognitive capacities such as planning, inhibition of dominant responses, flexibility, and working memory.

Barnes and Dennis (2001) have shown that, in addition to a deficient inferential ability, also a reduction of working memory and metacognitive skills may be invoked to explain closed-head injured children's problems in comprehending stories. Working memory provides the necessary resources for computing inference in ongoing text comprehension; metacognitive skills are used when checking if, and when, an inference needs to be made. The authors tested children with severe to mild head injury on their ability to comprehend brief written stories, and found inferencing deficits in children with severe (but not with mild)

head injury; these children had problems linking their general knowledge to the particular wording of the text. In general, when the metacognitive demands and the pressure on working memory were reduced, children with severe head injuries did not show any deficiencies in inferencing compared to the development in normal children or their mildly head-injured peers. Working memory also plays a role in explaining the poor ability to comprehend written stories that is observed in children with hydrocephalus, a neurodevelopmental disorder accompanied by increased pressure of the cerebrospinal fluid on the brain tissue. Children with hydrocephalus, when compared to the control group, show increasing difficulty drawing on information from an earlier read sentence when trying to understand a new sentence, the greater the distance between the two texts. Thus, while these children do not seem to have a fundamental problem in making inferences, their poor performance is mainly due to a deficit in their working memory (Barnes *et al.*, 2004).

As to the role of other executive functions, Channon and Watts (2003) examined the ability of CHI patients to comprehend brief vignettes involving pragmatic judgement and the relationship between this activity and some executive functions: working memory, inhibition, and the ability to organize and plan appropriate responses in a certain context. The authors found that only the ability to solve the inhibition task, which required the subjects to inhibit dominant words and generate words that completed sentences with nonsensical endings, correlates with the pragmatic comprehension task. No association was found with the other executive skills.

From a neuropsychological perspective, intact frontal lobes are critical to executive functioning, and because traumatic brain injury often results in damage to these areas, pragmatic deficits shown by these patients can be explained by a principal Executive Function impairment. From this perspective, the deficits in planning and monitoring of behavior that are usually observed in such patients seem to explain the difficulty these subjects have in adhering to the structure of conventional discourse (McDonald and Pearce, 1998).

To conclude, theoretical and empirical studies in the literature seem to suggest that in order to explain people's pragmatic competence, it is necessary to take into account the role played by at least three elements: mental processes, namely, the inferential load and the complexity of the mental representations; the Theory of Mind; and the Executive Function. Whereas the empirical studies mainly focus on the linguistic competence that is needed to realize various pragmatic tasks, the perspective should be widened to include

a methodical comparison with extralinguistic competence. In order to establish whether, or not, the cognitive components that make these two different means of communication are the same in both cases. Finally, a complete theory in the cognitive pragmatic domain should be able to explain not only adult normal subjects' ability to communicate, but also the development and the decay of this capacity in brain-damaged patients.

Cognitive Technology

Cognitive Technology (CT) as a Scholarly Discipline

The primary area of inquiry is Technological Cognition (TC), which examines what happens to humans when they augment themselves with technologies, either physically or cognitively, to amplify their natural capabilities. The aim of CT/TC is to formulate and to test theories of human cognitive processes that interact with technological artifacts and are partially formed by those interactions. As a fluid, symbiotic hybrid of the embodied mind and its tools, such a technologized cognition has epistemic effects: It affords an understanding and control of the external world that otherwise would not have been possible. As rational agents, humans develop and use tools to empower themselves in the *real* world which exists independently of them. This places CT/TC firmly in the realist tradition, in direct contrast with the assumptions of postmodernism: if the external world were merely a social construct, where reality is reduced to, and interpreted as, *text*, tool augmentation other than that related to natural language (e.g., metaphor) would be superfluous and CT/TC would lose its *raison d'être*. The belief that the human mind is molded by tools and open to scientific scrutiny also dissociates CT/TC from any theoretical framework that is essentially behaviorist in nature.

Methodology for Tool Design

Dialectic adaptation of the mind to the operations of its tools – a process that is often tool-coerced – leads to technological change. Increased technological sophistication forces us to make ethical choices. Of interest here is a search for design methods and practice capable of eliminating, before they even arise, any undesirable effects of tool use on users. The main question is “Which design methods and practice will result in tool-mind-world hybrids that optimally benefit humankind?” CT, understood as a methodology for design, is thus a process: an approach to design, not a product of such a design. We can design tools in accordance with CT principles, informed by the theoretical developments of TC, but those tools are not in themselves instances of CT.

The search for ethical factors in tool design means that studies undertaken within CT are primarily about people and not about the technologies that augment them. This distinguishes CT

from investigations of the so-called human factors in designing human-centered systems that promote ‘naturalness’ in human-tool exchanges and aim at designing ergonomic, user-friendly tools, in order to fully accommodate the limits of human performance and fully exploit the advantages of the user (as it is practiced in areas such as Cognitive Ergonomics, Cognitive Engineering, and Engineering Psychology). What such practices do not overtly address is the question of who really stands to benefit. Nor do they explicitly consider that every tool is a prosthetic device (some mental functions become redundant), that the user/tool relation is of one-to-many (with the dangers of stress overload), that sophisticated tools can obscure dignity at work, that they separate people from their natural habitat or change their perception of their own competence. By contrast, CT aims to bring humane factors to bear on design. The tool-mind-world hybrids designed according to the principles of CT are intended to be essentially anthropocentric, i.e., they maximize human (user) benefits (see Figure 1).

Mind-Amplifying Tool

CT takes a broad view of technology. All artifacts are in some measure cognitive tools. We need to understand them in terms of their goals and computational constraints as well as in terms of the external physical and social environments that shape and afford cognition. Any technology that serves that purpose by providing a tool has implications for CT/TC.

Cognitive tools can be situated on a continuum of purposeful use between the extremes of raw material and the brain. They can be more or less externalized or detached from the brain or the body (cf. bionic prostheses incorporating direct brain implants with word processors vs. spades). The greater the detachment, the lower the brain-tool connectivity and alignment. The lower the connectivity, the lower the ability to attend to the feedback the brain receives at

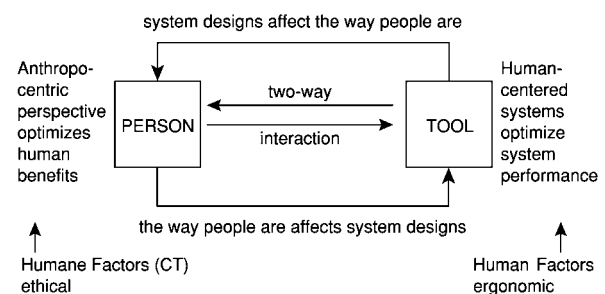

Figure 1 Anthropocentric CT design versus traditional human-centered design.

the interface; consequently, the less the need for people to adapt to the tool. Within this continuum, we can distinguish between natural technologies and fabricated technologies.

Natural Technologies

Natural technologies are instances of mental *techné*, i.e., learned skills and mental competencies. Examples proposed within CT include a body image generator responsible for perceiving one's own body size, the cognitive processes within the prefrontal cortex responsible for our social competence, or the cognitive processes evolved in autism. Here also belong learned aspects of natural language (see Whorf, Benjamin Lee), narratives, mnemonic systems for improving memory, task-dedicated cognitive processes in logic and arithmetic, or metaphors in cultural heritage. The mind itself can be viewed as a complex, goal-driven toolkit of natural cognitive artifacts that bootstrap on what is hard-wired, in order to make available a much bigger set of such artifacts. The mind thus facilitates interactions with the environment through the organization and integration of perceptual data, memory, and goal-management.

Fabricated Technologies

While some fabricated technologies are tangible (pens, paper, computers, mechanical gadgets, telecommunication devices, medical equipment, or flight simulators are obvious examples), others are not, but nonetheless they affect our mental capabilities and competences: e.g., writing systems, narratives, artificial languages, and so on.

Cybernetic systems such as robots can become a scientist's cognitive tools if they are built to further scientific progress. They have been applied to understand how categorical perception works, how intelligence of natural systems is embodied, and to the question of whether there is a fundamental distinction between humans and machines. In artificial intelligence, computation has been employed to formulate and to test theories of intelligence or the nature of consciousness. In computational linguistics, automated grammars have aided linguists in their efforts to understand the workings of natural language.

Any systematized environment that constrains cognition results in cognitive change. Perhaps the best example is a prison system where people become habituated to its inherent operations; many are unable to function effectively upon release. Or, take an organizational merger: Its most challenging aspect is consolidating the diversity of employees' mental cultures.

Perspectives on Mind Change

The simplest form of cognitive change is learning, and many technologies are purposefully developed to this end. While people will adapt to any technology, the extent of their adaptation depends on the extent of the cognitive fit between the human mind and the augmenting technology. When some mental processes are taken over by technology, the relevant natural technologies augment, too. A subsequent absence of the tool may then render the acquired *techné* ineffective. (As an example, consider the impact of word processors on generating texts.) Such a technological augmentation is not permanent and can be unlearned.

Technological augmentation can also have lasting effects. Longitudinal studies in archaeology reveal that cognitive fluidity can be directly linked to tool use. Studies in primatology and developmental psychology show that language constructs, in particular storytelling, played a crucial role in handling the complexity of the social dynamics responsible for the evolution of the primate brain. Social and narrative intelligence requires a larger neocortex, hence a bigger brain size.

Can we predict *a priori* the long-term effects of a given technology on the human user? The difficulty of this question has been recognized with respect to language. The meaning of a linguistic symbol depends on how, and in which context, it is used (see Context, Communicative; Wittgenstein, Ludwig Josef Johann). Language becomes alive and unfolds its history via its interaction with people. Meanings transform across different epochs and different cultures as a result of interpreting and reinterpreting language. The context of its use, and the medium through which it is used, have a bearing on language itself. Consider the impact of the Internet and mobile phones (texting) on the art of conversation or the spelling of words. The same is true of any artifact. Internal structure of design and a form perceived at the interface are insufficient to derive the social and personal significance or the subsequent development of a piece of technology. The latter can only happen in the context in which it is used. In the absence of such context, there is no unique answer to the question "What is this artifact for?" Its affordances for action (the toolness of a tool) only become manifest when the mind comes in contact with it in some context.

To predict the consequences of tool use, it is necessary (though not sufficient) to understand the social, psychological, and cognitive mechanisms that create the need for technological augmentation. A theoretical framework with a potential for such investigations must necessarily deal with motives

and benefits, in other words, with *relevance*. Within CT, the Theory of Relevance, originally developed with respect to language use (see **Relevance Theory**), has been broadened to encompass all cognitive processes (symbolic and connectionist) involved in action planning and goal management. This extended framework can be invoked to explain the modularity of mind and remove a variety of difficulties experienced in the symbol-driven acquisition of natural technologies or the design of fabricated ones. It provides grounds for classifying a dedicated inferential comprehension module as an instance of natural CT. By recognizing a multitude of cognitive interfaces (e.g., between perception, consciousness, knowledge, motivation, emotion, action, natural/fabricated technologies, external situations), the extended framework can assist the exploration of (1) the extent to which the constraints on our mental life are biologically or technologically determined, and (2) how language *techné* interacts with other aspects of cognition, facilitating, ultimately, the choice between various proposals for developing a humanized linguistic technology. Even so, the big question, whether, and to what extent, technology can be humanized, remains an open question (see **Adaptability in Human-Computer Interaction**).

Comics, Pragmatic Aspects of

K-A L Mey, Carmel, Calif, USA

© 2006 Elsevier Ltd. All rights reserved.

A comic (plural: comics), also known as (a) comic strip(s), is a narrative form that combines written text (see **Text and Text Analysis**) and pictorial elements.

A comic consists of a series of interrelated picture/text combinations. Each single picture stands in direct relation to the preceding units; this sequential order constitutes a chain of reference. Comparable to other serial productions of mass media such as soap operas or book and film series, comics have a continuous cast of main characters. The fact that the reader is

familiar with the protagonists' background serves as another important point of reference.

Comics either appear as regular strips in printed media (comic strips), in comic magazines with contributions by various authors, or as comic books featuring a main character and his or her story or episodes.

Origins of the Comics

Although the historic roots of comics can be traced back to the 18th and 19th centuries, to political cartoons and illustrated narratives such as *Max und Moritz* (1865) by Wilhelm Busch, comics in their modern form are a relatively recent phenomenon. At the end of the 19th century, American newspapers included comic strips in their Sunday supplement to attract more readers. These humorous picture-stories, also known as 'the funnies' or comic strips, gave their name to a new genre (see **Genre and Genre Analysis**), the comics, which is not restricted to funny stories only.

Narrative Means: How Comics Tell a Story

Is there a language specific to comics? At first sight, expressions like 'zoom,' 'growl!' and 'splash!' are likely to be identified as typical expressions of comic-language. While such expressions are certainly characteristic of the medium, they do not touch its essence. Among the great variety of narrative means of the comic, the most important feature is the interdependence of the illustrations and written text. Both elements are bearers of meaning, but it is their **combination** that makes up the narrative.

While the narrative may have any imaginable content – there are adventure stories, political satire, family series, the classical Greek mythologies and the Bible retold, comics for children, so-called adult comics with erotic or pornographic components, etc. – what all comics have in common is the use of this specific means of telling a story.

A comic consists of minimally two picture-text units, called panels. Panels are usually square boxes containing an image and sometimes text, bounded by a thin frame line. These panels are to be read in sequential order, comparable to a normal text, and this sequential relation distinguishes a comic from a mere accumulation of pictures. This sequence distinguishes a comic from a cartoon, which consists of a single picture-frame only.

If a comic is to be read like a text, the author has to create coherence within the story. He achieves this by forming a 'chain of reference.' This chain of reference will enable the reader to recognize the different panels

as narrative elements of the same story, comparable to the process of reading a text – the reader knows that the preceding words of a sentence are connected to the following words and will create a coherent narrative (see **Pragmatics of Reading**).

To illustrate this, let's imagine an episode with the world's most famous duck, Walt Disney's Donald Duck. A first panel might show Donald Duck sitting on a bench; the second one, Donald walking through a park; the last one, Donald in front of a house.

Theoretically, the reader could interpret this pictures as three separate pictures: 'Donald sits on a bench' / 'Donald takes a stroll in the park' / 'Donald stands in front of his/a house.'

But the reader knows, by means of identical reference, that every Donald appearing in the panels following the first panel is the same protagonist in the same story. That way, the reader can fill in the narrative gaps and verbalize this sequence of panels as 'Donald sat on a bench and walked home through a park.' As most readers will be familiar with the small suburban house that Donald lives in, the author can draw on this familiarity with Donald's surroundings as a further point of reference.

This system of reference is based on two *narrative strings*. One string refers to the space or environment where the action occurs, the other refers to the action itself.

In this way, once introduced, the environment 'park' remains valid until a new environment appears. The depiction of the park can be reduced to a single tree, a meadow, a flower – it may even disappear entirely, with no harm done to text comprehensibility, as the reader will still know the setting to be a park.

The other string deals with the *action*. Here, too, an element, mostly a living being such as Donald Duck in the example above, refers to its first introduction and can be reduced in various ways, e.g., to a silhouette, a hand, a hat floating on the water (as will happen to such an unlucky person as Donald). The separation between these two narrative strings, environment and action, is not absolute, though; an element of the environment can become bearer of an action, for instance, when a rock gives up its function as environment and falls down to block the road instead. Conversely, Donald's car can change function: when he parks it in front of his house and walks away, the car becomes part of the environment and is no longer an element of the action string.

In comics, a story can do without a description of the environment, but not without action. However, even though the description of action thus has priority over that of the environment, the latter has another, equally important function: it determines the rhythm of the narrative. An environment drawn in

every detail will slow down the narrative rhythm, since the reader is likely to spend more time contemplating the picture and to study all the details shown, whereas a picture stripped of all environmental details will speed up the pace of the narration (see below, Narrative Rhythm).

Playful Conventions: How to Read the Narrative Codes

Most readers of comics have been familiar with the genre since childhood, hence know to decipher the conventions of the codes specific to comics. There is no prescriptive list of given codes, comparable to punctuation in a written text, such as periods or commas. While certain conventions have been established, each author still has the freedom to disregard them, to play with them, and to invent new means of structuring a story – the only constraint being that the reader still must be able to grasp the meaning.

Common Narrative Codes in Comics

Arrangement of Panels Panels are usually arranged in sequential order, to be read from left to right and top to bottom, according to the usual direction of reading of the Latin alphabet. Deviations are marked by numbers or by arrows indicating the new direction. Deviations of the ordinary sequential pattern are often used to express the rupture of the normal (i.e., linear) flow of narrated time and space, for example, to illustrate simultaneous action or a particular protagonist's train of thought, as in daydreaming. Panels may have subpanels. A large panel may take up an entire page in a comic book, or be divided into subpanels forming a whole; so-called split-panels are arranged to show the details of an action happening, comparable to slow motion in a film.

Panel Frame The panel frame usually consists of a straight line forming a square frame. It indicates the boundaries of the image-text component. The form of the frame is included in the playful way that comics handle narrative conventions. The frame will become more than a mere designating line and start being a bearer of meaning, for instance, when a story within a story is being told. A flashback is marked by wavy or punctuated frame lines, zigzagging lines will express strong emotions or pain. Irrespective of its shape, the frame's function becomes clear within the entire context. Some authors will occasionally omit the frame altogether. By doing so, they strip the topic of its environmental context. Thus, they create a moment of concentration, the effect resembling a close-up in film. Because almost anything goes in this genre

(as long as the readers can construct meaning from the context), there are even authors that do without frames altogether.

Balloons Balloons are another vital constitutive element of the comic's narrative codes. They contain words or thoughts attributed to figures in the panel, and indicate who is speaking or thinking. The basic form of the balloon is a round or square frame containing the text; it usually hovers above the speaker's head like a small cloud, a small tail pointing to the speaker's head.

Balloons containing speech are conventionally drawn with a continuous line; balloons containing thoughts replace the balloon-tail by a line of bubbles. Thought-balloons are mostly used for characters that cannot speak in real life, such as animals, e.g., Jim Davis' 'Garfield,' the cat. There are, of course, infinite variations on this theme: whispering is illustrated by an interrupted line; a zigzagging balloon-tail indicates a voice as heard over a telephone; a balloon in zigzag-shape shows the speaker to be very angry; little icicles hanging on the balloon's lower frame lines indicate words spoken in mood; a balloon wreathed in flowers shows the character's effort to sweet-talk someone.

Colored comics will add color to their balloons and thus enhance the emotional impact of the text spoken or thought. A green balloon will signify envy, a red one anger or pain. A black balloon may even be drawn to resemble a somber storm cloud looming above the character's head, showing his or her dark mood.

Several balloons in a panel, as in a dialog, are to be read according to the direction of reading. Balloons can also contain symbols such as a light bulb (inspiration), a heart (love), or a saw (emulating the sound of snoring).

Written Text

There are three main groups of written text in comics:

- a. text within a balloon
- b. text within the panel
- c. text at the edge of, or between panels, so-called caption texts.

Text Within a Balloon Written texts in comics not only transmit their message by the words themselves, but also through the typographical appearance of the lettering. The latter is especially the case for the first two kinds of text mentioned, (a) and (b).

One important feature of the balloon text is its size. Small letters in a relatively oversized balloon indicate a low voice or a whisper; big letters, almost bursting

out of their balloon, indicate a loud voice or scream. The size of the lettering thus compensates for the absence of sound in the comic medium.

Various kinds of typography can be used to characterize the speaker. Comic author Walt Kelly, for instance, does this with great artistic subtlety in his story 'Pogo' (cf. Figure 1). This example shows three types of balloons as well as three types of lettering. The tortoise shown in the first panel is communicating in thought-balloons, according to the convention that animals do not speak. The letters are written in the widely used conventional capitals.

The second panel contains the balloon with the monologue of the deacon, a stiff-upper-lip persona forced to do kitchen-chores ("me, an administrative advisor, put to work peeling knockwursts and other vegetables"). His speech is contained by an ornamental balloon-frame, resembling ancient parchments. The letters are written in an accordingly old-fashioned way, made to resemble Gothic type, using capital and small letters.

Note, in the third panel, how small the letters '— sigh —' appear in the balloon. The last panel introduces an even different type of balloon; it is drawn to resemble a small cloud emerging from the bag containing the sausages and it contains the word

'chomp!' (an expression that combines the verb and the sound – see the next section).

So, just like the form of the panel or the balloon, the form of the letters, too, can bear meaning. Words cried in anguish will appear shaky or fragmented; old-fashioned typography and ornamental lettering is used to evoke an atmosphere of once-upon-a-time.

Text Outside Balloons Since comics cannot represent sound, they make it visible. This is achieved with the aid of sound-imitating or -describing words, also called onomatopoeia – the 'zoom,' 'growl!' and 'splash!' mentioned above. Whenever the text is not confined to the balloon, there are even fewer limits on the imagination of the author as to their typography. As in the balloon texts, big-sized lettering indicates loudness.

The source of the sound can be inferred from its position in the panel. 'Plitch,' a sound describing a dripping faucet, will appear near the surface that the water drop falls on. Some authors draw onomatopoeia with such expressiveness that these become pictures in themselves, e.g., a 'bouumm!' with exploding letters.

These expressions are often based on the imitation of sound, such as the just mentioned 'bouumm!' that

Figure 1 In Walt Kelly's 'Pogo,' the lettering is masterfully used to carry meaning. (Kelly, 1972: 120). Copyright 2000 OGPI.

evokes the sound of an explosion. Often, a verb is shortened into a descriptive form that describes the action, as in 'drip,' 'sob,' 'cracklerattlebash!' Not to forget the innumerable possibilities of combinations of both sound, verb, and description, as the above mentioned 'chomp!' or the sound of a starting racing car: 'vroummmroarr!'

Note that a loud cry can take on the quality of a sound word, drawn without a balloon ('yikes!!').

Caption Texts Caption texts are explanatory texts located at the edge of the panel (or between panels), often in a small, square frame of their own. They comment on the progress of the story in the panel and give information that has not been conveyed by the panels. The function of the caption text is to link the panels, sum up or comment on the action, or provide any information the author wants to communicate to the reader. They frequently deal with time factors, e.g., they could read 'later,' 'meanwhile,' or 'ten years ago.'

Pictorial Signs

Apart from the narrative means of structuring a story listed above, comics dispose of a large variety of pictorial signs. These signs appear as illustrations of the action taking place in the panel; often they are used to show a protagonist's emotional state or his or her general condition. Such illustrations are often graphical translations of a figure of speech, such as 'having a broken heart' or 'if looks could kill' – the lovelorn protagonist will have a splintered heart hovering above his or her head in the first case, whereas small daggers will be drawn on their way from the protagonist's eyes towards his or her adversary in the latter.

Great effort, embarrassment, and alarm are universally shown by little drops of perspiration flying from the protagonist's head (as in sweating, due to physical exertion, or breaking out in cold sweat). Pain is depicted by stars appearing above the hurting part of his or her body; feeling dizzy, being drunk or knocked-out, by spirals around the head (cf. above about 'balloons': hearts, light bulbs, etc., within the balloon).

Apart from these mostly figurative illustrations, comics have developed a specific graphic feature to show movement. They are called 'speed lines' and refer to the slurring of vision to the eye when an object or person moves in fast motion. Speed lines will trail along a speeding object, telling the onlooker 'it was here just a second ago, but it moved over there within the blink of an eye.' Speed lines will show the course of the moving object; often, they are accompanied by small dust clouds to enhance the effect.

Doing without Sound and Motion: Narrative Rhythm

Every narrative is told in segments. An author will select which segments of a progression he or she will show or tell and leave gaps in between for the reader to fill in and make up a continuous narrative flow (see *Narrative Means: How Comics Tell a Story*, above). The pace of a narration is directly related to the number of panels; an event illustrated by many panels will naturally slow down the narrative rhythm, whereas inserting a caption reading 'two weeks later' above a panel speeds it up. The narrative rhythm is not related to the time narrated (see *Narrativity and Voice*).

Apart from the numbers of panels, the narrative rhythm can also be varied by other means: by drawing a detailed environment (usually in a panel that is comparatively larger than the others), or by zooming out into a wide angle, as is often used in films to mark a moment of introduction or contemplation at the beginning or ending of a film. These wide angle shots are, for instance, used as recurring features in Goscinny & Uderzo's 'Asterix the Gaul.' The story usually starts with a large introductory panel, a wide angle shot of the 'small village in Gaul,' depicting a pastoral idyll, and it ends invariably with a panoramic view of the villagers enjoying themselves at a big banquet under the starry sky (with the unmusical bard being tied to a tree in the foreground, in most of the cases).

Equally, comics will make use of the other possibilities of film language, as it is expressed in the way a camera shot is taken. One of the factors involved is distance. A panel can show a small human silhouette in the distance, in the vast landscape of a desert plain. Or it can show only a detail of that person's face e.g., a pair of frightened eyes, seen from very short distance. The close-up shot will let the reader be part of the protagonist's emotional state of mind, whereas the first example keeps the reader more at a distance.

Apart from distance, the virtual camera can choose a particular angle to convey the narrative's message. A character shown from below will appear as someone superior and in control, someone looked down upon will appear as just that. Clever authors even make use of the subjective camera, known from experimental films. Thus, in 'Asterix and the Normans' a teenage boy from the capital Lutetia is sent to a remote small village 'to become a man.' He gets caught by the fear-inspiring Normans, knocked over the head and falls unconscious. The Normans splash water on him and in the following panel we see what the frightened boy sees: A close-up of a row of awe-inspiring beards as seen from lying on the ground, all nasty smiles and helmets, looking very grim indeed.

Communication: Semiotic Approaches

E Rigotti and S Greco, University of Lugano, Lugano, Switzerland

© 2006 Elsevier Ltd. All rights reserved.

The Rise of a Controversy

The topic at issue in this article shows several problematic aspects. In communication research, we are presently crossing a phase of intensive innovation, in which the paradigm and the role of the different disciplines are changing remarkably. For a long time, the leading role in this area was played by the *sciences du langage*, in particular by semiotics and linguistics. Nowadays, this role is played by a complex epistemological interplay, where other human and social sciences – focusing on the organizational assets of communication context – as well as technological disciplines contribute to the study of real communicative events. Thanks to these contributions, it has become evident that real communicative events are not only influenced, but functionally governed by their actual context (enterprises, institutions, communities, and other social organizations ...) and by the media, by which they are not only broadcasted, but also structured.

Moreover, even linguistic sciences, which are expected to explain the internal structure of a communicative event, are largely adopting a model of communication whose conceptual frame is no longer essentially semiotic, but rather pragmatic. The prevailing of a pragmatic paradigm seems to have strongly redimensioned the semiotic claim. More specifically, both major trends – Speech acts Theory and Relevance Theory (i.e., the ostensive inferential model of communication) – are proposing a vision of communication that does not focus on semiotic aspects.

While the former of these trends has developed its own model essentially ignoring the semiotic approach (Austin, 1962 and Searle, 1969), the latter has created

a proper controversy, initiating a sort of campaign against the semiotic approach and its academic power.

At this point, it is useful to outline the ostensive-inferential model of Relevance Theory synthetically, in order to specify its criticism of the semiotic model of communication, and also what it justly presupposes a semiotic model to be. In fact, the ostensive-inferential model, whose roots are Paul Grice's and David Lewis' works (Sperber and Wilson, 1995/1986: 2) is introduced by means of those aspects that oppose it to the semiotic model (Sperber and Wilson, 1986: 6) "The semiotic approach to communication (as Peirce called it and we will call it ourselves), or the semiological approach (as Saussure and his followers called it), is a generalization of the code model of verbal communication to all forms of communication," and is thus to be abandoned, since it does not seem to explain the real functioning of communicative events: "The code model of verbal communication is only a hypothesis, with well-known merits and rather less well-known defects. [...] Its main defect, as we will shortly argue, is that it is descriptively inadequate: comprehension involves more than the decoding of a linguistic signal" (Sperber and Wilson, 1995/1986: 6). In other words, the semiotic approach appears to interpret communication as a process where a speaker constructs a message by coding a certain meaning by means of a linguistic system, and transfers it to a hearer who simply **decodes** it, thus retrieving its original meaning. The roles of the speaker and the hearer in a communicative event are thus reduced to coding and decoding respectively. The scholars of the ostensive-inferential approach to communication, relying on wide and unquestionable evidence, argue that the process of interpreting a message by the hearer is far more complex, and that the semiotic component represents a rather short stretch of the communicative process.

The semiotic component is neither necessary nor sufficient to explain the process of communication.

Firstly, it is not necessary because many messages do not make use of a linguistic system; very often, the communicator addresses the hearer not through words of a certain natural language, or through another semiotic system, but through traces by which the hearer is expected to be guided to infer the communicative intention of the message. Sperber and Wilson (1995/1986: 25) argued in fact that Grice's originality consisted in suggesting that the identification of the communicator's intentions is **sufficient** for the achievement of successful communication, and the mediation of a verbal code is not necessarily needed. The authors give an example (Sperber and Wilson, 1995/1986: 25–26) that shows how communication may succeed even without the help of the coding-decoding process. If Peter asks Mary: 'How are you feeling today?', Mary may answer by pulling a bottle of aspirin out of her bag and showing it to him. Although there is no code or convention that rules the interpretation of her behavior, this action can be taken as strong evidence that she wants to inform Peter that she does not feel well. In this sense, Mary and Peter can be said to have communicated, even if they have not made use of any verbal or nonverbal code.

The semiotic component is not even sufficient, even in the very usual cases where it is present. However large it may be, interpretation requires that various contextual aspects are involved in order to complete the information carried by the semiotic component: "Verbal communication is a complex form of communication. Linguistic coding and decoding is involved, but the linguistic meaning of an uttered sentence falls short of encoding what the speaker means: it merely helps the audience infer what she means" (Sperber and Wilson, 1995/1986: 27). Within this complex form of communication, the results of the decoding process are considered a piece of evidence from which the hearer, through a noncoded mechanism, can infer the speaker's intentions. In this sense, the semiotic component becomes subservient to the inferential process. Using the terminology of Relevance Theory, an enrichment of the linguistic form of the message is however indispensable to obtain the semantic and pragmatic interpretation of a message. This is crucial to distinguish between 'sentence' and 'utterance of a sentence.' According to these authors, generative grammars fail to consider that a certain sentence may appear in an enormous variety of utterances that, though sharing a 'core of meaning' (Sperber and Wilson, 1995/1986: 9) bound to the linguistic code, each includes a different non-linguistic, context-bound meaning that can be neither

predicted nor 'calculated' through a decoding process. Therefore, an inference process is required in order to grasp a complete representation of the communicator's intentions. To give just an example (adapted from Sperber and Wilson, 1995/1986: 11), a sentence like 'You're leaving' contains different levels of noncoded meaning: (1) an indexical (you) whose interpretation depends on the actual communicative event where the sentence is uttered; and (2) a set of possible interpretations: is the speaker informing the hearer that she is to leave? Is she making a guess? Or is she rather expressing disappointment because he is leaving?

Thus, the process of comprehension, through which the hearer reconstructs the communicator's intentions, is not a decoding process, but rather an inferential process. Whereas the decoding process "starts from a signal and results in the recovery of a message which is associated to the signal by an underlying code" (Sperber and Wilson, 1995/1986: 13), an inferential process starts from a set of premises and reaches a conclusion warranted by the premises themselves. Among possible interpretations of an utterance, the hearer chooses the most adequate to certain expectations of truthfulness, informativeness, and comprehensibility. The inferential process of comprehension is an essential component of communication, which is nonetheless often integrated by the employment of a code. A common code between the interlocutors turns out to be the most powerful, however not indispensable, tool for communicating.

Sperber and Wilson's critical remarks are generally convincing and acceptable, where they criticize the attempt to explain the interpretative process merely in terms of decoding. Less convincing is the more general criticism of all semiotic models of communication, accusing them of reducing communication to a coding and decoding process.

Saussurean 'Signification' as Keyword and Sign of Contradiction

Our thesis is that Sperber and Wilson's criticism, which is legitimate in relation to certain semiotic models, is unacceptable for others. Furthermore, in our opinion, their reductive vision of the function of the semiotic component within a communicative process is by no means convincing.

For both points, we should briefly reconsider some of the communication models more or less explicitly proposed by semioticians and linguists in the past century. It is almost compulsory to start by referring to Ferdinand de Saussure, with whom the beginning of modern linguistics in its structuralist phase is usually connected. His representation of the

Figure 1 Ferdinand de Saussure's model.

communication process seems to constitute a typical coding and decoding model, **Figure 1**.

Here the speaker, having in mind a particular *signifié*, correlates it to the corresponding 'signifiant' of her linguistic system (*langue*), which is perceived by the hearer who correlates it to the correspondent *signifié* of the same linguistic system. Nonetheless, Saussure's *Cours* is of a problematic nature; its real function is to bear witness to a deep and complex meditation rather than systematically expounding a theory. Thus, beyond the approximate presentation of the discourse circle (*circuit de la parole*), the Saussurean text introduces the fundamental but problematic distinction between *signifié* – defined as a meaning carried by an element of a *langue* (a linguistic system) – and *signification* – a term denoting a notion that remains rather opaque in the Saussurean text. Its interpretation and the evaluation of its role in Saussure's doctrine is nevertheless crucial, and turned out to characterize the two main divergent trends that emerged within post-Saussurean structuralism. It is worth noticing that these two trends have developed considerably different attitudes toward communication in their theoretical elaboration. Relevant representatives of both trends being numerous, only those scholars who cover significant and universally acknowledged points of controversy will be mentioned here.

The Functionalist Reading

Let us consider Saussure's text. In a passage in chapter IV of the second part of the *Cours de linguistique générale* (1916/1995: 158–159), Saussure seems to employ the term *signification* as equivalent to *signifié*: *signification* seems to be nothing but the counterpart of the auditive image, "*un des aspects de la valeur linguistique*" or, better, the value of the conceptual component of the linguistic sign. Nonetheless, in the following passages, Saussure opposes *signification* to *signifié* throughout a series of interlinguistic confrontations (*mouton* vs. *sheep* and *mutton*, French plural vs. Sanskrit plural and dual, etc). So, without explicitly saying it, Saussure employs *signification* as opposed to *signifié*; interlinguistic comparisons between different language-bound *signifiés* are possible thanks to a conceptualization of reality that is formed

somehow independently of these *signifiés*. This distinction lets us guess the existence of a complex correlation between the two semantic dimensions (reasonably understood as interpretation), which goes from the *signifiés* obtained through the coding to the *significations*, which articulate the *parole* (the speaker's actual message). Without this conceptualization, evoked by the use of the term *signification*, such a comparison between different languages would be simply impossible (on this point, see Rigotti & Rocci, in press). *Signification*, thus, has to be interpreted as an inter- or translinguistic category independent of the linguistic code, however correlated to it. If we integrate this notion into the Saussurean *circuit de la parole*, we obtain a more comprehensive model of communication, where the correlation of *signifiant* and *signifié* is only a stretch of a more complex path, starting with the actual meaning intended by the speaker, and ending with the reconstruction of this meaning tentatively operated by the hearer.

The interpretation of the Saussurean text presupposed by this model is explicitly adopted by N. Troubezko in his *Grundzüge der Phonologie* (1939), where the *signifiés* are considered, at the level of *langue*, as abstract rules and conceptual schemes, which need to be related to the actual *significations* emerging from language use (see also Rigotti & Rocci, 2006: 5). On this point, M. Bréal (1844–1995: 552b) observes that, where we need to employ a certain word in communication, we 'forget' all possible meanings of that word except the one that corresponds to our thought ("*s'accorde avec notre pensée*"). Although the other meanings are still somehow present to our mind, we choose the one that corresponds to the meaning we want to express – i.e. to the *signification*. Here, the relation between *signifiant* and *signifié* is certainly not a coding-and-decoding one, since it is mediated by the speaker's choice to her communicative intention. The same approach to communication may be found in Karl Bühler's *Organonmodell*, as outlined in his *Sprachtheorie* (1934). Among the numerous pages of Bühler's text, which could be useful to elucidate his position on this issue, one passage seems particularly revealing (1934: 63), where Bühler argues that no code can ensure the correct interpretation of the word 'horse' as it is used in a text, where it can refer to a single entity or to the species of horses in general. The use within a text is not "*morphologisch erkennbar*," i.e., it cannot be decoded by means of morphological properties of the language, neither in Latin, a language that does not possess articles, nor in any (Indo European or other) article-provided languages. What allows us to correctly interpret the use of the word 'horse,' is a 'detective-attitude' towards the

context of the communicative event, which aims at evaluating what the speaker has in mind: “Man muss es detektivisch gleichsam dem Kontexte oder den Umständen der Sprechsituation entnehmen, ob der Sprecher das eine oder das andere im Auge hat und meint.” Moreover, an author to whom Bühler is quite indebted, Philipp Wegener, had also stressed the interpretative aspect of communication 50 years previously. Wegener argues that the hearer has the complex task of understanding the speaker’s action; for this purpose, he has to figure out what the ‘goal’ of the communicative action may be. Comprehension of verbal messages is achieved through ‘inferences’ (*Schlüsse*), which rely both on the meaning of the verbal signs and on the experience of reality. So, where experience is lacking, comprehension is impossible (Wegener, 1885–1991: 128). For instance, one could not understand a sentence such as ‘a whistle of the train, and my brother was gone,’ if one had no experience of a train setting off from a station.

If, speaking of a semiotic approach to communication, we refer to this research tradition in linguistics and semiotics, the criticism put forward by the scholars of Relevance Theory loses its bite: in fact, the process of communication is not referred to as a coding-decoding process within this trend. Rather, one should acknowledge that the process of communicative inference is constantly associated with the concept of interpretation.

Nor would the objection be acceptable that, in these models, inference only plays the subservient role of integrating the semiotic process. Here, it must be noticed that, if inference is acknowledged as a necessary integration of the semiotic component, it follows that the semiotic component itself is not considered sufficient for the accomplishment of the communicative event. Therefore, the inferential component becomes essential for communication. More specifically, in this first tradition, neither the speaker’s coding nor the hearer’s decoding hold the supremacy in the communicative process; the crucial moment is rather when it becomes clear what the speaker intended to communicate, and the hearer understands it. As Bühler claims, on the backdrop of a Husserlian philosophical vision, language always appeals to the speaker’s knowledge of reality; and each time we understand the meaning of a communicative event, we deeply and unavoidably rely on a ‘reality-driven selection’ (*sachgesteuerte Selektion*, Bühler, 1934: 65), which constitutes the core of communication. Not by chance, a large part of Bühler’s research is devoted to the study of the specific semantic mechanism of the ‘indexicals’ or ‘deictics’ (*Zeigwörter*). This term refers to linguistic units and structures whose meaning is reconstructed through the identification of an aspect

of the communicative situation (Bühler, 1934 see in particular p. 107).

Here, given the importance that Bühler attributes to reality in the process of communication, it becomes clear why he adopts a ‘triadic’ notion of the sign, which is rather innovative if we compare it to other structuralist models. In his *Organonmodell* (1934: 24), the sign is conceived as an ‘instrument’ for communicating; and communication is interpreted pragmatically, as an action accomplished by the speaker and the hearer. According to Bühler (1934: 52), communication must be viewed as a human ‘action,’ vitally bound to other meaningful human behaviors. Communication is related to other actions, and is an action in itself. In particular, Bühler distinguishes between *Sprechhandlung* (1934: 53), which is the human activity of communicating, i.e., the Saussurean *parole*, as opposite to *Sprachgebilde* (the *langue*, 1934: 57); moreover, with the notion of *Sprechakt* (1934: 62), he focuses on a single communicative action, and with *Sprachwerk* (1934: 53), he denotes the linguistic products resulting from a single human action of communicating.

Within the model, the sign is related to the speaker (*Sender*), the addressee (*Empfänger*) and the objects and states of affairs in reality (*Gegenstände und Sachverhalte*). The sign is bound to each dimension by a specific relation: with regard to the speaker, the sign is a ‘symptom,’ bound by a relation of ‘expression’ (*Ausdruck*); with regard to the addressee, the sign is a ‘signal,’ and stands in the relation of appeal (*Appel*); and, finally, with regard to the object, the sign is a ‘symbol,’ and stands in the relation of ‘representation.’ The following diagram, **Figure 2**, illustrates Bühler’s model (1934: 28):

The distinction between code dimension and discourse dimension of semantics, implied by the Saussurean terms *signifié* and *signification*, is tackled and deepened by another linguist: E. Benveniste, who introduced the terms ‘semiotic’ and ‘semantic’ (Benveniste, 1966a). He underlines that the content dimension of code units is a semiotic one; while the content dimension of the same units, insofar as they are used within a discourse, is truly semantic (on this point, see also Rocci, 2003). Moreover, among the indexicals investigated by Bühler, he focuses on personal pronouns, by which the communicative act and its constituents are mirrored in specific linguistic structures (Benveniste, 1966b). The study of personal pronouns on both the diachronic and the synchronic axes brings Benveniste to single out the essential role that is played by subjectivity (*I* and *You*) in communication.

On the basis of the Saussurean notion of ‘signification,’ conceived as the actual, situation-bound

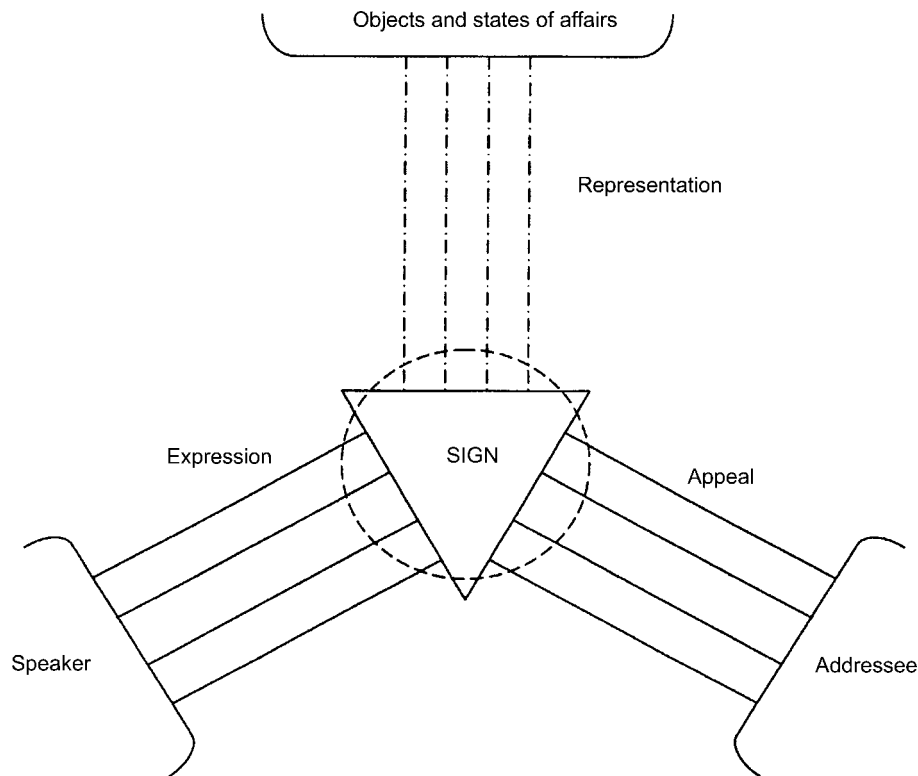

Figure 2 Karl Bühler's *Organonmodell*.

Figure 3 The model of communication within the functionalist reading.

meaning of the sign in the communicative process, and of Bühler's interpretation of the sign as an instrument for communicating, we could modify Saussure's diagram and build a model of communication that is shared in its fundamental aspects by all the authors within the research tradition we have examined so far, **Figure 3**.

Even in its visual diversity, the well-known model proposed by Roman Jakobson (Jakobson, 1960/1995) is, in many respects, reminiscent of Bühler's sign model. Being evidently influenced by Shannon

and Weaver's model, it brings to light the process of transmitting a message, thus offering a rather obvious metaphor of the communicative process, **Figure 4**.

Jakobson's model has two indubitable merits: firstly, it takes into account, and represents synthetically, a complex set of factors; secondly, it deepens many of the specific functions of the message in relation to each of these factors in the communication process. This Russian linguist treasures his former belonging to the significant experience of Russian formalism, by introducing the poetic function into his model, as an

Figure 4 Roman Jakobson's model of the fundamental factors of communication.

Figure 5 Roman Jakobson's model of the textual functions.

autotelic orientation of the message towards itself, **Figure 5.**

The graphic representation of Jakobson's model appears to be richer than the sign scheme provided by Bühler. However, if we consider the model implicit in the theory of the latter, we have to recognize that Bühler's model is richer in important respects: indeed, in Jakobson's perspective, the pragmatic dimension is weakened; the essential role of inference in interpretation is ignored, as well as the relevance of context for interpretation. Another important aspect concerns the distinction between *signifié* and *signification*, reflecting the more general difference between language (*langue*) and speech (*parole*), which remains outside the graphic model outlined by Jakobson, even though it is adumbrated in some significant research (Jakobson, 1957).

Some Code-model Approaches

The precise definition of the Saussurean model represents a core issue for a large segment of semioticians of the past century. Indeed, besides the tradition we have tackled so far, another tradition of semiotic studies starts from a different interpretation of Saussure's *signification*. The second trend does not concentrate on the notion of *signification*, and therefore it does not focus on the textual and discursive dimension of the *parole*, whereas the point of view of the code (*langue*) is preferred. This position can be found not only in Hjelmslev's *Prolegomena to a theory of language* (1961), but also in various scholars belonging to French structuralism – among which R. Barthes plays a paradigmatic role – and in Umberto Eco's first semiotic theory, expounded in his work *Trattato di semiotica generale* (1979).

It is worth noticing that it is quite difficult to infer a model of communication from these positions.

Barthes, for instance, stresses the interpretation of language as a system, whereby the individual performing a particular act of *parole* (a discourse) simply selects and actualizes one of the possible states of the system (Barthes, 1964). As the semantic dimension is exhaustively represented by the system of the *signifiés*, the meaning of communicative messages is not built by a speaker for an addressee, but it is rather one possible product the system can generate. The human subject is excluded from the communication process; communication itself, conceived as a communicative interaction between two human beings, i.e., as the junction of the communicative action of the speaker with the interpretative action of the addressee, fails to be considered at all. Umberto Eco (1979: 8) defined communication as “the passage of a signal (*not* necessarily a sign) from a source (through a transmitter, along a channel) to a destination.” This definition is meant to include both cases of machine-to-machine passages of information (see also 1979: 32), and cases where the destination (and not necessarily the source) is a human being. In the latter case, communication involves the process of signification, “provided that the signal is not merely a stimulus but arouses an interpretive response in the addressee” (1979: 32). The process of signification is not conceived as a communicative action; the focus here is on the signification system, “an autonomous semiotic construct that has an abstract mode of existence independent of any possible communicative act it makes possible” (1979: 9). Thus, it is the system that guarantees communication, and the existence of the system does not presuppose the existence of actual communicative events. On the contrary, communication between human beings necessarily presupposes a signification system (thus excluding cases of nonverbal, ostensive communication). It must be observed that Eco explicitly discusses the problem of what the place of the human being, i.e., “the ‘acting subject’” (1979: 314) within semiotics should be. He concludes that what is outside the signification system – its “material expressions” (1979: 317) might even be “tremendously important,” but it is beyond the subject of semiotics. In fact, as Eco argues, the proper subject of signification is “nothing more than the continuously unaccomplished system of systems of signification that reflects back on itself,” whereas individual material subjects only “obey, enrich, change and criticize” the signification system (1979: 315).

As emerges from our survey of some theories within the second trend of Saussurean semiotics, speaking of a proper ‘model of communication’ in relation to them turns out to be quite difficult. In fact, communication in itself is intrinsically ignored. What they hypothesize are the mysterious workings

of an autonomous semiotic program, which would auto-install and run on a great number of undifferentiated terminals, thus defining their individual or network sign production.

Charles Sanders Peirce

The model of communication of the first trend inspired by Saussurean semiotics, which we found in Bühler, and which is confirmed by recent pragmatic models, shows interesting analogies with another tradition, often considered as alternative to the Saussurean one: the semiotic model by Charles Sanders Peirce. As Bühler would do in the 1930s, Peirce had already proposed a triadic notion of sign at the end of the 19th century, **Figure 6**.

According to what Peirce wrote in 1897 (1897–1935–1958: 2.228), “A sign, or ‘representamen’ is something which stands to somebody for something in some respect or capacity. It addresses somebody, that is, creates in the mind of that person an equivalent sign, or perhaps a more developed sign. That sign which it creates I call the interpretant of the first sign.” Although Peirce is often considered one of the founders of semiotics, it must not be forgotten that his contribution is particularly relevant from the logical and philosophical points of view. And his interest for semiotics concerns the cognitive rather than the communicative dimensions. Nonetheless, his contribution is also significant for semiotics and for a theory of communication. Concerning semiotics, we have to underline that Peirce’s notion of sign includes ‘symbols,’ as well as ‘indexes’ (bound to the object through a real connection), and ‘icons,’ which remind of objects by reproducing their features. Semiotics turns out to include both verbal and nonverbal dimensions. Nevertheless we should also consider that, within Peirce’s enormous scientific production, we find some significant cues for a significantly comprehensive communication model.

Firstly, the correlation of the sign with both subjectivities involved in communication is highlighted by the above-quoted definition, where the subject to whom the sign is addressed is explicitly mentioned

Figure 6 Charles Sanders Peirce’s model of sign.

and the addresser is presupposed. On this point, M. Hansen (2002) argued that Peirce’s approach implies an active involvement of the speaker and the addressee in the process of interpretation. In fact, the ‘representamen’ does not univocally imply a certain ‘interpretant,’ but it rather suggests several possible interpretations. Here, the interaction of the speaker and the addressee is necessary to evaluate the interpretation to be chosen: the context of interpretation is actively constructed by the interlocutors, on the basis of the experience of the knowledge community.

Secondly, we find in the Peircean text a truly pragmatic reading of the process of interpretation, as the ‘final interpretant’ of a sign is the ‘habit change,’ i.e., “a modification of a person tendencies toward action” (Peirce, 1897–1935–1958: 5.476; on this point, see also Rigotti & Rocci, 2001: 48).

Concluding Remarks

We might conclude by arguing that the criticism raised against the semiotic tradition by the scholars of Relevance Theory is only valid for those semiotic approaches which can be defined as code-driven, and depend on a reductive interpretation of Saussure. They conceive of the sign as a binary unit, and thus reduce communication to a coding and decoding process. The criticism does not hold for all those, indeed rather numerous, approaches (Peirce and the functionalist interpretation of the Saussurean *Cours*: Troubetzkoy, Bühler, Jakobson, Bally, Sechehaye, Karcevskij ...), where a pragmatic (in the sense of the *Organonmodell* of language) and triadic representation of the sign allows one to understand communicative events in an adequately comprehensive perspective.

Our short survey of semiotic approaches to communication in the 20th century shows that not all of them can be considered as code-models, it also puts forward – this concerns in particular some authors like Peirce, Bühler, and Benveniste – the possibility and even the reasonableness of constructing a semio-pragmatic model of communication (Searle, 1969; Clark, 1996), concerning both the wording and the interpretation side, this latter being based on semiotic, metaphoric (Lakoff, 1980; Danesi, 2004) and inferential processing (Sperber and Wilson, 1995–1986); comprehending both verbal and nonverbal communication (Rocci, 2003), and including a theory of subjectivity as one of its relevant components (see Rigotti and Cigada, 2004). And the semiotic tradition of the 20th century could be shown to be helpful in this endeavor.

Communicative Competence

T M Lillis, The Open University, Milton Keynes, UK

© 2006 Elsevier Ltd. All rights reserved.

The phrase 'communicative competence' was introduced by the North American linguist and anthropologist, Dell Hymes, in the late 1960s (Hymes, 1962/1968, 1971). He used it to reflect

the following key positions on knowledge and use of language:

- The ability to use a language well involves knowing (either explicitly or implicitly) how to use language appropriately in any given context.
- The ability to speak and understand language is not based solely on grammatical knowledge.

- What counts as appropriate language varies according to context and may involve a range of modes – for example, speaking, writing, singing, whistling, drumming.
- Learning what counts as appropriate language occurs through a process of socialization into particular ways of using language through participation in particular communities.

Hymes's juxtaposition of the word 'communicative' with 'competence' stood in sharp contrast at the time with Noam Chomsky's influential use of the term 'linguistic competence,' which Chomsky used to refer to a native speaker's implicit knowledge of the grammatical rules governing her/his language (Chomsky, 1957, 1965). Such knowledge, Chomsky argued, enables speakers to create new and grammatically correct sentences and accounts for the fact that speakers are able to recognize grammatically incorrect as well as correct sentences such as, in English *She book the read*, or in Spanish *plaza yo a la voy* ('square I am going to'). While accepting the importance of grammatical knowledge, Hymes argued that in order to communicate effectively, speakers had to know not only what was grammatically correct/incorrect, but what was communicatively appropriate in any given context. A speaker therefore must possess more than just grammatical knowledge; for example, a multilingual speaker in a multilingual context knows which language to use in which context and users of a language where there are both formal and informal forms of address know when to use which, such as *vous* (formal) and *tu* (informal) in French. Hymes famously stated that a child who produced language without due regard for the social context would be a monster (1974b: 75).

The emphasis that Hymes placed on appropriateness according to context, in his use of the term competence, challenged Chomsky's view about what exactly counts as knowledge of a language – knowledge of conventions of use in addition to knowledge of grammatical rules. In addition, and more fundamentally, Hymes problematized the dichotomy advanced by Chomsky between 'competence' and 'performance' and the related claim about what the study of linguistics proper should be. Chomsky's interest was in the universal psycholinguistics of language, the human capacity for generating the syntactic rules of language. His interest in knowledge, captured in his use of 'competence,' was therefore at an ideal or abstract level rather than in any actual knowledge that any one speaker or group of speakers might possess. For Chomsky, the focus of linguistics as a discipline should be on understanding and describing the general and

abstract principles that make the human capacity for language possible. In contrast, 'performance' or actual utterances – that is, what people actually say and hear with all the errors, false starts, unfinished sentences – could add little to an understanding of the principles underlying language use and was therefore not deemed to be a relevant focus of linguistic study.

Hymes acknowledged the value of the more abstract and idealized approach that Chomsky advocated, not least because such a universalistic approach challenged any theories of language based on genetic differences or notions of racial hierarchy (Hymes, 1971: 4). However, he argued that there were other important dimensions to the study of language that should not be so readily excluded from linguistics as a scientific field. Hymes's own interest in language was in large part driven by a concern for language questions arising in real life contexts, such as why children from economically advantaged and disadvantaged social backgrounds differ in the language they use. Chomsky's and Hymes's different aims for developing language theory are nowhere more clearly evident than in Hymes's comment on Chomsky's (1965: 3) now famous statement, on the purpose of linguistic theory: "Linguistic theory is concerned primarily with an ideal speaker-listener, in a completely homogenous speech-community, who knows its language perfectly..." Hymes (1971: 4) comments: "The theoretical notion of the ideal speaker-listener is unilluminating from the standpoint of the children we seek to understand and to help."

Hymes was highly critical of a theory that explicitly set out to ignore the impact of social context on how language is used and hence the competence/performance dichotomy set up by Chomsky (echoing in some ways the *langue* and *parole* distinction made by Saussure, 1916). At a specific level, his key reasons for challenging such a dichotomy can be summarized as follows (based on Hymes, 1962/1968; 1971; 1974b):

- The dichotomy itself is problematic. It presupposes that knowledge can be understood without reference to use, yet analyzing actual use of language is key to exploring underlying principles for such use. Hymes argued that "performance data" should be considered a legitimate focus for linguistic study both in its own right and as data that reflects knowledge underlying any performance.
- The dichotomy is built on a series of abstractions: ideal speaker-listener, homogenous speech-community, perfect knowledge of language.
- Chomsky's notion of speaker-listener does not acknowledge or account for the differences in

reception competence and production competence evident in many contexts, as in children from some social backgrounds understanding formal school language yet not producing it.

- What counts as knowledge of language is reduced to only one aspect of knowledge, namely grammatical knowledge, when there are clearly other aspects to knowledge of language that are important, such as when to use which language, or varieties of languages, and in which contexts.
- Within an approach that focuses on competence as idealized knowledge, it is the abstract system of language that becomes the focus rather than speakers'/groups of speakers' use of language.
- Given the focus on knowledge as a set of abstract rules underlying use, actual use is relegated to only a marginal position in the scientific study of language.

Hymes (1972a: 282) offers communicative competence as a more general and superordinate term to encompass the language capabilities of the individual that include both knowledge and use: "competence is dependent upon both (tacit) knowledge and (ability for) use."

While Hymes argued against the foundational dichotomy between competence and performance proposed by Chomsky, he was not dismissing the value of the distinction entirely. Hymes refers to communicative competence as "abilities in a broad sense" of how to use language, whereas performance is always a specific use of language that reflects some of that competence (2003: 321). Thus any specific performance may partially reflect the nature of the conventions governing an individual or a community's knowledge of language. In setting up a framework for developing an adequate theory of language, Hymes argued that both what is known (competence) and what is actually done (performance) must be taken into account. Such a framework involves exploring and accounting for the following:

1. Whether (and to what degree) something is formally possible
2. Whether (and to what degree) something is feasible
3. Whether (and to what degree) something is appropriate
4. Whether (and to what degree) something is in fact done, actually performed (Hymes 1972a: 284–286).

Questions 3 and 4 are central to the socially oriented approach to the study of language advocated by Hymes. In contrast to Chomsky and his claim to linguistics as a subfield of psychology and

philosophy, Hymes seeks to claim a space for the study of language within "a science of social man" (Hymes, 1971: 6).

A Key Concept in an Emerging Sociolinguistic Tradition

Emphasis on the notion of communicative competence formed part of Dell Hymes's call for a new field of study, the ethnography of communication, sometimes called the ethnography of speaking (Hymes, 1962/1968; Gumperz and Hymes, 1972/1986). There are a number of concepts and categories presupposed by the notion of communicative competence, which continue to be highly influential in sociolinguistics and in many socially oriented approaches to study of language.

Sociocultural Context

Given the importance attached to knowledge of the social conventions governing language use, understanding the context of language use is considered to be central. Exploring such context, that is, the cultural, historical, and social practices associated with the language use of any particular group or community of people, involves detailed descriptions and classification of language use organized around the following key questions. What are the communicative events, and their components, in a community? What are the relationships among them? What capabilities and status do they have, in general and in particular cases? How do they work? (Hymes, 1974b: 25).

Ethnography of Communication

In order to explore how language is used in context, Hymes argued for an ethnographic approach to the study of communication or ways of speaking (Hymes, 1974a). This involves researchers setting out to systematically observe the activities of any given community, through immersing themselves in such activities and collecting a range of data, such as recordings, field notes, and documentation. In this methodology both 'etic' and 'emic' approaches are considered important and complementary; the etic approach refers to observation from the outside as it were, that is, the researcher seeks to observe in detail the communicative activities – or speech events – of participants in a community; the emic involves exploring such events, from the inside, to determine how participants make sense of and understand such events and interactions. Ethnographers emphasize the importance of emic accounts to any theory of language; for example, only an emic perspective would enable a researcher to understand that a clap

of thunder may in some cultural contexts be considered to be a communicative act (as in the case of the Ojibwa reported by Hymes, 1974b: 13), or that certain types of communication are permitted to men in some contexts while proscribed in others, such as the disciplining of children (as reported by Philipsen, 1975).

In an attempt to build a descriptive framework of how language is used in different contexts, Hymes, drawing on anthropologists such as Malinowski (1923, 1935), developed a series of categories to map out the relevant contextual aspects to language use, such as speech event and speech community.

Speech Event

This is a category (after Jakobson, 1960) that reflects the idea that all interaction is embedded in sociocultural contexts and is governed by conventions emerging from those contexts. Examples of speech events are interviews, buying and selling goods in a shop, sermons, lectures, and informal conversation. The speech event involves a number of core components identified by Hymes, which are signaled in his mnemonic device SPEAKING. [See Table 1].

Speech Community

While the term speech community was not coined by Hymes (the most notable earlier use being that of Bloomfield, 1933), Hymes's elaboration of the term certainly contributed to its prominence in sociolinguistic approaches to the study of language.

The acquisition of communicative competence takes place within speech communities: speech communities are constituted not just by a shared variety or language, but shared sets of norms and conventions about how those varieties can and should be used. Through everyday interaction with others in a speech community, a child learns how to use language appropriately, that is, according to the norms of any given speech community. Some events inevitably involve people from different speech communities, which may create tensions: as in for example school classrooms where participants share a common language but may not be members of the same speech community (Hymes, 1972c).

Diversity

Acknowledgement of diversity and variety between and across language use, in communities and individuals, is a basic position in Hymes's work and is a central tenet in sociolinguistics. Such diversity manifests itself in countless ways: the very existence of language varieties, both as languages and varieties within languages; the range of conventions

Table 1 SPEAKING – acronym invented by Dell Hymes (1972b) to specify relevant features of a speech event

S-settings and scenes	Setting refers to time, place, physical circumstances. Scene refers to the psychological or cultural definitions of the event: for example what 'counts' as a formal event varies from community to community.
P-participants	Who is involved, as either speaker/listener, audience.
E-ends	Ends can be defined in terms of goals and outcomes. Goals refer to what is expected to be achieved in any event: outcomes refers to what is actually achieved. Goals and outcomes exist at both community and individual participant level: for example, the conventional goal of a wedding ceremony may be marriage, however, individuals within that event may have other goals.
A-acts	Speech events involve a number and range of speech acts, particular types of utterances such as requests, commands, and greetings.
K-keys	The tone, manner, and spirit in which acts are done, for example, serious or playful. Specific keys may be signaled through verbal or/and non-verbal means.
I-instrumentalities	The particular language/language varieties used and the mode of communication (spoken, written).
N-norms	Norms of interaction refer to rules of speaking, who can say what, when, and how. Norms of interpretation refer to the conventions surrounding how any speech may be interpreted.
G-genres	Categories or types of language use, such as the sermon, the interview, or the editorial. May be the same as 'speech event' but may be a part of a speech event. For example, the sermon is a genre and may at the same time be a speech event (when performed conventionally in a church); a sermon may be a genre, however, that is invoked in another speech event, for example, at a party for humorous effect.

governing the use of such varieties in different contexts (such differences have been documented in relation, notably, to social class, ethnic group, gender); the different values attached to particular usages (for example, the values attached in different communities to such phenomena as silence, eloquence, and interruptions).

Privileging diversity as a universal of language shifts the emphasis away from any differential status attached to varieties, or the notion that difference signals deficiency in any way. All varieties are seen

as equally valid, although some are acknowledged to be more appropriate in particular contexts.

Appropriateness

This is a key presupposition to the notion of communicative competence and is a central notion in sociolinguistics. As discussed, communicative competence presupposes the following; that a language user's knowledge – competence – is more than just grammar-based; that knowledge of language requires knowledge of the appropriate social conventions governing what and how something can be said, to whom and in what contexts. Appropriateness thus involves both linguistic and cultural knowledge (Hymes, 1971: 14).

Within sociolinguistics, a focus on appropriateness of language use is said to indicate a descriptive (how language is used) rather than a prescriptive (how language should be used) approach to language diversity.

Socialization

People learn the rules of use through everyday interaction within speech communities. It is through such interaction that children acquire knowledge about appropriate language use, that is, communicative competence (Hymes, 1971: 10). Hymes indicates that socialization is not constituted by a rigid trajectory and suggests that both “a long and short range view of competency should be adopted” (1972a: 287). From his perspective, the short range view concerns innate capacities as they emerge in the first years of life, and the long range concerns continuing socialization through life. What this short/long range implies is that competence is not static. In some instances, quite drastic changes can be made to an individuals' competence; as when a child whose home language variety is significantly different from the school variety. Of course, as Hymes emphasizes, such extensions or shifts in competence are not necessarily straightforward; there are plenty of opportunities for misunderstanding to occur when receivers/listeners accustomed to the language varieties of one community engage in communication with those from another.

Communicative Competence in Other Domains

The notion of communicative competence has been highly influential in fields beyond linguistics, such as education, sociology, and psychology. In some instances the basic assumptions surrounding the term have been maintained, and in others extended or problematized.

Probably nowhere has the impact of the notion been more powerful than in the teaching of languages, including the teaching of English as a second or foreign language. Whereas the emphasis in language teaching had been on grammatical and syntactic accuracy, following the work of Hymes and others (Gumperz and Hymes, 1972/1986), there was a significant turn towards communicative language teaching; this shift involved the teaching and learning of language considered to be appropriate to specific situations, based on what speakers actually use, rather than what they are presumed to use (Paulston, 1992). Assessment of language learning has been influenced accordingly, with a focus on students' capacity to communicate, rather than the ability to produce grammatically correct sentences (Hall and Eggington, 2000). The extent to which this more situational approach to second and foreign language teaching prevails is a matter of debate, but the impact of communicative competence is widely acknowledged (Firth and Wagner, 1997).

The use of the term has also been extended and modulated in other domains. For example, Culler (1975) developed the influential notion of literary competence to describe readers' knowledge of the conventions required in order to interpret literary texts. Academic communicative competence has been used to refer to knowledge of the conventions governing the use of language in academic communication (Berkenkotter *et al.*, 1991). Both uses refer to knowledge of specific textual features, such as metaphor in the case of literary competence and argument in academic competence, as well as knowledge about what counts as specific text types or genres (academic, literary) in particular cultural contexts.

Other uses of ‘communicative competence’ have developed, alongside and in contradistinction to the Hymesian term. Habermas (1970) uses the term communicative competence more in line with Chomsky's linguistic competence, to the extent that he is interested in theorizing an ideal speech situation, rather than elaborating a sociolinguistic description of actual situations and utterances. In contrast, Bernstein's interest was in an elaboration of actual use of language, particularly within the context of schooling. However, he offered a critique of the way in which ‘competence’ models implied an exaggerated capacity of individual rational choice and control over language use, without due attention to “distribution of power and principles of control which selectively specialize modes of acquisition and realizations” (Bernstein, 1996: 56). The need to theorize power in relation to competence and language use is a key

strand in other studies re-examining the notion of communicative competence in more recent times.

Re-examining Communicative Competence

The work of Hymes is central in sociolinguistics as a field and continues to reverberate across socially oriented approaches to the study of language in a range of disciplines, including applied linguistics, education, communication studies, and social psychology. In recent times, there have also been significant re-examinations of communicative competence and related notions, as they have come to be used in sociolinguistics, from both critical and post structuralist approaches.

Re-examining Appropriateness

The notion of appropriateness is central to communicative competence and central to the field of sociolinguistics whose empirical goal has been to explore patterns of language use, according to the norms of any given community. However, the use of such a notion has been critiqued by some because it serves to emphasize norms and underplay differences within any given community or communicative context. Fairclough (1995), for example, like Bernstein mentioned above, argues that a model of language based on appropriateness assumes shared views among all users about what counts as appropriate, ignoring struggles and tensions in any given interaction; for example, tensions evident in interactions between institutional representatives and clients, men and women, or speakers from different cultural and linguistic backgrounds. Research in some socially oriented approaches to language, such as feminist linguistics and critical discourse analysis, has made visible the power dynamics in communicative events, within and across communities (Cameron, 1992; Wodak, 1992; Chouliaraki and Fairclough, 1999).

In the same vein, emphasis on a normative notion of communicative competence in second and foreign language teaching has been critiqued by theorists of second language acquisition. Norton (2000) states that although it is important for learners to understand the conventions of the target language, it is also important for them to explore “whose interests these rules serve” (2000: 15). She argues that any definition of communicative competence should include an acknowledgement of the importance of the right to speak (Bourdieu, 1977); such a right to speak, or be heard, is not granted to all speakers in all contexts. Thus for example, immigrants using a foreign language may find that, although familiar with the

conventions governing a particular use of that language, they may not be granted the right to speak or be heard in some contexts.

Re-examining Speech Event and Speech Community

While Hymes always indicated that he used the word ‘speech’ to mean all types of communicative modes/channels, sociolinguistic research has tended to focus on the spoken word. In more recent times, explicit attention has been paid to other modes of communication, thus extending the use of core concepts. For example, those working within literacy studies have used existing terms to signal a specific focus, such as “writing event” (Basso, 1974), “literacy event” (Heath, 1983; Barton and Hamilton, 1998). Likewise, Swales (1990) has argued that the term discourse community is more useful than speech community, as a term for describing and accounting for practices around written texts. Some theorists have argued that the word ‘speech’ signals that language is considered more significant than other practices, or that language is somehow divorced from other social purposes and activities, and have argued that the notion of practice, including the notion of “community of practice” is more all encompassing and powerful (Eckert and McConnell-Ginet, 2003; see also discussion about ways in which ‘practice’ is used in Schultz and Hull, 2002).

A more fundamental challenge to the notion of speech community comes from theorists emphasizing the ways in which recent historical changes, notably globalization, powerfully influence the ways in which people engage in the world and disrupt traditional notions of community and community membership. Through a whole range of technological, social, and economic developments – shaping modes of labor, travel, and communication – individuals’ relations to others are more diverse and fluid, less restricted by time and space. The extent to which speech community with any presumed identifiable boundaries continues to be a meaningful category of observation and analysis is debatable within the context of a rapidly changing world (Rampton, 1998; Collins, 2003).

Re-examining the Notion of Speaker

Just as the notion of speech community has been challenged, so too have prominent labels used to categorize individuals in relation to communities – such as social class, ethnicity, linguistic repertoire, and gender. Such terms, because they often denote fixed sets of attributes and capacities, have been recognized as problematic, particularly by post structuralist writers who stress that identity is always

in process. Indeed, the relationship between language and identity has established itself as a key area for research. Such work tends to challenge the idea that language use reflects categories of identity (I speak as I do because I am a working class woman) and emphasizes, rather, how individuals actively construct aspects of social and personal identity through their use of language in specific contexts (in speaking as I am, I am constructing and representing myself as a working class woman). While it is recognized that such constructions of identity are not free floating but are regulated by the specific contexts and interactions in which they occur (Cameron, 1997a), the fluidity of identity tends to be emphasized. In these approaches, the term 'performativity' rather than 'performance' is used, in order to signal how identity is enacted or performed through interaction (Cameron, 1997b; Butler, 1990/1999).

Re-examining Context

The work of Hymes placed the importance of context centrally within the concern of linguistics and advocated ethnography as the key organizing methodological tool with which to observe language use. However, there has been considerable debate about what constitutes context and how context should be conceptualized and explored. Two significant and quite distinct approaches to the study of context can be found in conversation analysis and critical discourse analysis: the former orients inwards as it were towards language, the latter orients outwards towards the social world. Conversation analysts argue that speakers construct and represent relevant aspects of context through their actual interaction and that these can be empirically observed (Schegloff, 1997). In contrast, critical discourse analysts (Fairclough, 1995) and feminist linguists (Cameron, 1992) have signaled the limitations to approaches that seek to understand context through empirical observation alone: there have been calls to draw on social, critical, and post structuralist theorists and philosophers such as Foucault, Habermas, Bourdieu, and Bakhtin, in order to explore the ways in which language use is related to ideology and power, and in order to explore how phenomena such as globalization are influencing communicative practices. Some of this work tends to explore language use through the lens of such theory and pays only minimal attention to examining contexts empirically (Chouliaraki and Fairclough, 1999), whereas others drawing on ethnographic traditions such as Hymes's, aim to establish an approach that draws on both empirical observation and specific aspects of social theory (Rampton, 1995; Lee, 1996; Maybin, 1999). Attempts have been made to integrate levels of

analysis at the macro level of society with micro levels of actual utterances; Gee (1996) for example uses the terms big 'D' discourse to refer to the former and little 'd' discourse to refer to the latter; Fairclough (1992) has developed a three-layered framework to explore such relations, which he refers to as a textually oriented discourse analysis (TODA).

Communicative Language Teaching

S J Savignon, Pennsylvania State University,
University Park, PA, USA

Communicative language teaching (CLT) is best understood within the broader historical spectrum of methods or approaches to language teaching. Seen from a 21st-century modernist perspective that

views teaching as rather more science than art, the theoretical grounding for the epistemology of practice offered by CLT can be found in (1) the second- or foreign language acquisition research that began to flourish in the 1970s and (2) a long-standing functional view of language and language use as social behavior. The interpretation or implementation of practice in language teaching contexts around the world is, of course, yet another matter. A consideration of

these various influences highlights the major issues that confront CLT in the early decades of the 21st century.

Linguistic Theory and Classroom Practice

The essence of CLT is the engagement of learners in communication to allow them to develop their communicative competence. Use of the term ‘communicative’ in reference to language teaching refers to both the process and goals of learning. A central theoretical concept in CLT is *communicative competence*, a term introduced in the early 1970s into discussions of language (Habermas, 1970; Hymes, 1971) and second-language learning (Jakobovits, 1970; Savignon, 1971). Competence is defined as the expression, interpretation, and negotiation of meaning and looks to second-language acquisition research to account for its development (Savignon, 1972, 1983, 1997). The identification of learner communicative needs provides a basis for curriculum design. Descriptors sometimes used to refer to features of CLT include: process-oriented, task-based, and inductive (or discovery-oriented).

The elaboration of what has come to be known as CLT can be traced to concurrent developments in linguistic theory and language learning curriculum design, both in Europe and in North America. In Europe, the language needs of a rapidly increasing group of immigrants and guest workers, along with a rich British linguistic tradition that included social as well as linguistic context in the description of language behavior, led to the development of a syllabus for learners based on notional-functional concepts of language use. This notional-functional approach to curriculum design derived from neo-Firthian systemic or functional linguistics that views language as meaning potential and maintains the centrality of context of situation in understanding language systems and how they work (Firth, 1937; Halliday, 1978). With sponsorship from the Council of Europe, a Threshold Level of language ability was proposed for each of the languages of Europe in terms of what learners should be able to *do* with the language (van Ek, 1975). Functions were based on the assessment of learner needs and specified the end result or goals of an instructional program. The term ‘communicative’ was used to describe programs that followed a notional-functional syllabus based on needs assessment, and the language for specific purposes (LSP) movement was launched.

Concurrently, development within Europe focused on the process of classroom language learning. In Germany, against a backdrop of social democratic concerns for individual empowerment articulated in

the writings of philosopher Jürgen Habermas (1970), language teaching methodologists took the lead in the development of classroom materials that encouraged learner choice (Candlin, 1978). A collection of exercise types for communicatively oriented English language teaching was used in teacher in-service courses and workshops to guide curriculum change. Exercises were designed to exploit the variety of social meanings contained within particular grammatical structures. A system of ‘chains’ encouraged teachers and learners to define their own learning path through a principled selection of relevant exercises (Piepho, 1974; Piepho and Bredella, 1976). Similar exploratory projects were also initiated by Candlin at his academic home, the University of Lancaster in England, and by Holec (1979) and his colleagues at the University of Nancy in France. Supplementary teacher resource materials promoting classroom CLT became increasingly popular (for example, see Maley and Duff, 1978). There was also a renewed interest in learner vocabulary building. The widespread promotion of audiolingual methodology with a focus on accuracy in terms of so-called native grammatical or syntactic form had resulted in the neglect of learner lexical resources (Coady and Huckin, 1997).

At about the same time, paradigm-challenging research on adult classroom second-language acquisition at the University of Illinois (Savignon, 1971, 1972) used the term ‘communicative competence’ to characterize the ability of classroom language learners to interact with other speakers and to make meaning, as distinguished from their ability to recite dialogues or to perform on discrete-point tests of grammatical knowledge. At a time when pattern practice and error avoidance were the rule in language teaching, this study of adult classroom acquisition of French looked at the effect of practice in the use of coping strategies as part of an instructional program. By encouraging learners to ask for information, to seek clarification, to use circumlocution and whatever other linguistic and non-linguistic resources they could muster to negotiate meaning, and to stick to the communicative task at hand, teachers were invariably leading learners to take risks, to speak in other than memorized patterns. Consistent with the process of language development that was being documented in first-language and untutored or ‘natural’ second-language acquisition research, the communicative activities offered learners an opportunity to focus on meaning as opposed to form. Achievement tests administered at the end of the 18-week introductory-level instructional period showed conclusively that learners who had engaged in communication in lieu of repeating laboratory

pattern drills performed with no less accuracy on discrete-point tests of grammatical structure. In fact, their communicative competence as measured in terms of fluency, comprehensibility, effort, and amount of communication in unrehearsed communicative tasks significantly surpassed that of learners who had had no such practice. Learner reactions to the test formats lent further support to the view that even beginners respond well to activities that let them focus on meaning as opposed to formal features.

A collection of role plays, games, and other communicative classroom activities was developed subsequently for inclusion in the adaptation of the French CREDIF materials, *Voix et Visages de la France*. The accompanying guide (Savignon, 1974) described the purpose of these activities as involving learners in the experience of communication. Teachers were encouraged to provide learners with the French equivalent of such expressions as 'What's the word for...?', 'Please repeat,' and 'I don't understand,' expressions that would help them participate in the negotiation of meaning. Not unlike the efforts of Candlin and colleagues working in Europe, the focus was on classroom process and learner autonomy. The use of games, role plays, pair, and other small group activities gained acceptance and was subsequently recommended for inclusion in language teaching programs generally.

The coping strategies identified in the Savignon (1971, 1972) study became the basis for the subsequent identification by Canale and Swain (1980) of strategic competence in their three-component framework for communicative competence, along with grammatical competence and sociolinguistic competence. Grammatical competence represented sentence-level syntax, forms that remain the focus of Chomskyan theoretical linguistic inquiry and were a primary goal of both grammar-translation and audio-lingual methodologies. Consistent with a view of language as social behavior, sociolinguistic competence represented a concern for the relevance or appropriateness of those forms in a particular social setting or context. There is now widespread recognition of the importance of these various dimensions of language use and of the need for learners to be involved in the actual experience of communication if they are to develop communicative competence.

Inclusion of sociolinguistic competence in the Canale and Swain framework reflected the challenge within American linguistic theory to the prevailing focus on syntactic features. Dell Hymes (1971) had reacted to Noam Chomsky's (1965) characterization of the linguistic competence of the "ideal native speaker" and had used the term 'communicative

competence' to represent the use of language in social context and the observance of sociolinguistic norms of appropriateness. His concern with speech communities and the integration of language, communication, and culture was not unlike that of Firth and Halliday in the British linguistic tradition. Hymes's communicative competence may be seen as the equivalent of Halliday's meaning potential. Social interaction rather than the abstract psycholinguistic functioning of the human brain would become an identifying feature of CLT. Interpreting the significance of Hymes's perspective for language learners, some U.S. methodologists tended to focus on 'native speaker' cultural norms and the difficulty, if not impossibility, of representing these norms in a classroom of 'non-natives.' In light of this difficulty, the appropriateness of communicative competence as an instructional goal for classroom learners was questioned (Paulston, 1974).

CLT thus can be seen to derive from a multidisciplinary perspective that includes linguistics, anthropology, philosophy, sociology, psychology, and educational research. Its focus has been the elaboration and implementation of programs and methodologies that promote the development of functional language ability through learner participation in communicative events. Central to CLT is the understanding of language learning as both an educational and a political issue. Language teaching is inextricably tied to language policy. Viewed from a multicultural, intranational, and international perspective, diverse sociopolitical contexts mandate not only a diverse set of language learning goals but also a diverse set of teaching strategies. Program design and implementation depend on negotiation among policymakers, linguists, researchers, and teachers. The evaluation of program success requires a similar collaborative effort. The selection of methods and materials appropriate to both the goals and context of teaching begins with an analysis of socially defined language learner needs, as well as the styles of learning that prevail in a given educational setting (Berns, 1990).

Emergence of English as a Global Language

Along with a better understanding of the second-language acquisition process itself, the emergence of English as a global or international language has had a profound influence on language teaching, confronting language teacher education with new challenges worldwide. With specific reference to English, CLT recognizes that the norms followed by those in the 'inner circle' of English language users, to adopt the terminology proposed by Kachru (1992), may not be an appropriate goal for learners

(Pennycook, 2001; Savignon 2001, 2002). In a post-colonial, multicultural world where users of English in the outer and expanding circles outnumber those in the inner circle by a ratio of more than two to one, the use of such terms as 'native' or 'native-like' in the evaluation of communicative competence has become increasingly inappropriate.

Learners moreover have been found to differ markedly in their reactions to learning a language for communication. Although some may welcome apprenticeship in a new language, viewing it as an opportunity, others experience feelings of alienation and estrangement. Such phenomena may be individual or general to a community of learners. In Spanish-speaking Puerto Rico, for example, a long-standing general resentment of U.S. domination exerts a powerful negative influence on English language instruction. Not only learners but sometimes teachers also may consciously or subconsciously equate communicative English language learning with disloyalty to the history and culture of the island. Studying the rules of grammar and memorizing vocabulary lists is one thing. Using English for communication in other than stereotypical classroom exercises is quite another. Where they exist, such feelings are a strong deterrent to second- or foreign language use, even after 10 or more years of instruction.

With respect to the documentation of cross-varietal differences of English, research to date has focused most often on sentence-level lexical and syntactic features. Consequently, such attempts as the Educational Testing Service (ETS) Test of English for International Communication (TOEIC) to represent norms for a standard English for international communication reflect a primarily lexical and syntactic emphasis (Lowenberg, 1992). The hegemony of essentially Western conventions at the levels of discourse and genre is represented or challenged less easily. Differences in the way genres are constructed, interpreted, and used of course clearly extend beyond lexical and syntactic variation. Such differences are currently thought of as discursive in nature and are included in discourse competence, a fourth component of communicative competence identified by Canale (1983). Pressures for a 'democratization' of discursive practices have in some settings resulted in genre mixing and the creation of new genres. In professional communities, however, conformity to the practices of an established membership continues to serve an important gate-keeping function. The privilege of exploiting generic conventions becomes available only to those who enjoy a certain stature or visibility (Foucault, 1981; Fairclough, 1992; Bhatia, 1997).

Sociocultural Competence for a Dialogue of Cultures

Consistent with a view of language as social behavior, sociolinguistic competence is as we have seen integral to overall communicative competence. Second- or foreign language culture and its teaching have of course long been a concern of language teachers. Yet, if early research addressed the possibility of including some aspects of culture in a foreign language curriculum (for example, see Lado, 1957), recent discussion has underscored the strong links between language and culture and their relevance for teaching and curriculum design (Valdes, 1986; Byram, 1989; Damen, 1990; Kramsch, 1993). So mainstream now is the view of culture and language as inseparable that the term "sociocultural" has come to be substituted for the term "sociolinguistic" in representing the components of communicative competence (Byram, 1997; Savignon, 2002; Savignon and Sysoyev, 2002).

Interest in teaching culture along with language has led to the emergence of various integrative approaches. The Russian scholar Victoria Saphonova (1996:62) has introduced a sociocultural approach to teaching modern languages that she has described as "teaching for intercultural L2 communication in a spirit of peace and a dialogue of cultures." Given the dialogic nature of culture (Bakhtin, 1981), we cannot fully understand one culture in the absence of contact with other cultures. Thus, dialogue can be seen to be at the very core of culture, where culture is understood as a dialogical self-consciousness of every civilization.

The emergence of a focus on sociocultural competence can be seen in other European nations as well. The free flow of people and knowledge within the European Union has increased both the need and the opportunity for language learning and intercultural understanding. Brammerts (1996:121) described the creation of the International E-Mail Tandem Network, a project funded by the European Union that brings together universities from more than 10 countries to promote "autonomous, cooperative, and intercultural learning." The project is an extension of the tandem learning initiated in the 1970s in an effort to unite many states in a multicultural, multilingual Europe. Collaboration between entire classrooms of learners is a focus of ongoing research (Savignon and Roithmeier, 2003; Kinginger, 2004).

Interpretations of CLT

Although the term CLT may be recognized worldwide, theoretical understanding and interpretations of it vary widely. Some methodologists have suggested that CLT is an essentially Western concept,

inappropriate in other than Western contexts (Richards and Rogers, 2001; Rao, 2002). In addition, there are those who consider discussions of CLT to be passé (Bhatia, 2003; Kumaravadivelu, 2003; Savignon, 2003, 2004). Discouraged by the failure of both grammar-translation and audiolingual methods to prepare learners for the interpretation, expression, and negotiation of meaning and yet encouraged to adopt a variety of commercial materials and strategies increasingly labeled 'communicative,' many teachers and even teacher educators have been left confused or disillusioned. Substantive revision of teaching practice appropriate to a given context is ultimately of course the responsibility of classroom teachers. Yet, they cannot be expected to change their practices without considerable administrative and governmental support along with extensive guided experiential pre-service and in-service professional development.

Given the current widespread uncertainty as to just what are and are not essential features of CLT, a summary description would be incomplete without brief a mention of what CLT is *not*.

CLT is not concerned exclusively with face-to-face oral communication; principles of CLT apply equally to literacy. Whether written or oral, activities that involve readers and writers in the interpretation, expression, and negotiation of meaning are in and of themselves communicative. The goals of CLT depend on learner needs in a given context. Although group tasks have been found helpful in many contexts as a way or providing increased opportunity and motivation for communication, classroom group or pair work should not be considered an essential feature of CLT and may well be inappropriate in some settings. Finally, CLT does not exclude metalinguistic awareness or conscious knowledge of rules of syntax, discourse, and social appropriateness. However, knowing a rule is no substitute for using a rule. The creative use of interpretive and expressive skills in both reading and writing requires practice. CLT cannot be found in any one textbook or set of curricular materials inasmuch as strict adherence to a given text is not likely to be true to the process and goals of CLT. In keeping with the notion of context of situation, CLT is properly seen as an approach or theory of intercultural communicative competence to be used in developing materials and methods appropriate to a given context of learning. No less than the means and norms of communication they are designed to reflect, communicative teaching methods will continue to be explored and adapted.

Considerable resources, both human and monetary, are being deployed around the world to respond

to the need for language teaching that is appropriate for the communicative needs of learners. In the literature on CLT, teacher education has not received adequate attention. What happens when teachers try to make changes in their teaching in accordance with various types of reform initiatives, whether top-down ministry of education policy directives or teacher-generated responses to social and technological change? Several recent reports of reform efforts in different nations provide a thought-provoking look at language teaching today as the collaborative and context-specific human activity that it is.

Redirection of English language education by Mombusho, the Japan Ministry of Education, includes the introduction of a communicative syllabus, the Japan Exchange and Teaching (JET) Program, and overseas in-service training for teachers. Previous encouragement to make classrooms more 'communicative' through the addition of 'communicative activities' led to the realization by Mombusho that teachers felt constrained by a structural syllabus that continued to control the introduction and sequence of grammatical features. With the introduction of a new national syllabus, structural controls were relaxed, and teachers found more freedom in the introduction of syntactic features. The theoretical rationale underlying the curriculum change in Japan includes both the well-known Canale and Swain (1980) model of communicative competence and the hypothetical classroom model of communicative competence, or the "inverted pyramid," proposed by Savignon (1983: 46).

Minoru Wada, senior advisor to Mombusho, described these efforts as "a landmark in the history of English education in Japan. For the first time it introduced into English education at both secondary school levels the concept of communicative competence. ... The basic goal of the revision was to prepare students to cope with the rapidly occurring changes toward a more global society" (Wada, 1994:1). Following the research model adapted by Kleinsasser (1993) to understand language teachers beliefs and practices, Sato (2002) reported on a year-long study of teachers of English in a private Japanese senior high school. Multiple data sources, including interviews, observations, surveys, and documents, offered insight into how EFL teachers learn to teach in this particular context. Among the major findings was the context-specific nature of teacher beliefs, which placed an emphasis on managing students, often to the exclusion of opportunities for English language learning.

Cheng (2002) has documented the influence of a new, more communicative English language test on the classroom teaching of English in Hong Kong,

a region that boasts a strong contingent of applied linguists and language teaching methodologists and has experienced considerable political and social transformation in recent years. In keeping with curricular redesign to reflect a more task-based model of learning, alternative public examinations were developed to measure learners' ability to make use of what they have learned, to solve problems, and to complete tasks. Cheng's ambitious multiyear study found the effect of washback of the new examination on classroom teaching to be limited. There was a change in classroom teaching at the content level, but not at the more important methodological level.

The case of such washback in Costa Rica, a small nation with a long democratic tradition of public education, offers a contrast with the Hong Kong study. Quesada-Inces (2001), a teacher educator with many years of experience, reported the findings of a multicase study that explored the relationship between teaching practice and the Bachillerato test of English, a national standardized reading comprehension test administered at the end of secondary school. Although teachers expressed strong interest in developing learner communicative ability in both written and spoken English, a reading comprehension test was seen to dominate classroom emphasis, particularly in the final two years of secondary school. The findings illustrate what Messick (1996) has called "negative washback," produced by construct under-representation and construct irrelevance. The Bachillerato test of English does not reflect the content of the curriculum, assessing skills less relevant than those that go unmeasured. The English testing situation in Costa Rica is not unlike that described by Shohamy (1998) in Israel where two parallel systems exist – one the official national educational policy and syllabus and the other reflected in the national tests of learner achievement.

English language teaching has also been a focus of curricular reform in both Taiwan and South Korea. Adopting a sociocultural perspective on language use and language learning as a prerequisite to pedagogical innovation, Wang (2002) noted the efforts that have been made to meet the demand for competent English language users in Taiwan. They include a change in college entrance examinations, a new curriculum with a goal of communicative competence, and the island-wide implementation of English education in the elementary schools. However, she noted that despite learner preference for a more communication-focused curriculum, grammar teaching continued to prevail and much more needed to be done to ensure quality classroom teaching and learning: "Further improvements can be stratified into three interrelated levels ... teachers, school

authorities, and the government. Each is essential to the success of the other efforts" (Wang, 2002: 145).

CLT in the 21st Century

In each of the studies sketched above, the research was both initiated and conducted by local educators in response to local issues. Although each is significant in its own right, together they can only suggest the dynamic and contextualized nature of language teaching in the world today. Nonetheless, the settings that have been documented constitute a valuable resource for understanding the current global status of CLT. Viewed in kaleidoscopic fashion, they appear as brilliant multilayered bits of glass, tumbling about to form different yet always intriguing configurations. From these data-rich records of language teaching reform in the early 21st century, three major themes emerge, suggestive of the road ahead:

1. The highly contextualized nature of CLT is underscored again and again. It would be inappropriate to speak of CLT as a teaching method in any sense of that term as it was used in the 20th century. Rather, CLT is an approach that understands language to be inseparable from individual identity and social behavior. Not only does language define a community but a community, in turn, also defines the forms and uses of language. The norms and goals appropriate for learners in a given setting, and the means for attaining these goals, are the concern of those directly involved.
2. Related both to the understanding of language as culture in motion and to the multilingual reality in which most of the world population finds itself is the futility of any definition of a 'native speaker,' a term that came to prominence in descriptive structural linguistics and was adopted by teaching methodologists to define an ideal for language learners.
3. Time and again, assessment seems to be the driving force behind curricular innovations. Increasing demands for accountability along with a positivistic stance that one cannot teach that which cannot be described and measured by a common yardstick continue to influence program content and goals. Irrespective of their own needs or interests, learners prepare for the tests they will be required to pass. High-stakes language tests often determine future access to education and opportunity.

Communicative Principle and Communication

I Kecskés, State University of New York, Albany

Inferential Nature of Communication

The main characteristic of human communicative behavior is that its major part takes place between the explicitly expressed words. Most of the time, there is a significant difference between what we say and what we mean. In spite of this, we usually have no difficulty figuring out what the speaker tries to communicate implicitly. Why is this so? According to Grice, the decisive feature of pragmatic interpretation is its inferential nature (Grice, 1961). He argued that most aspects of utterance interpretation that traditionally are regarded as conventional, or semantic, should be treated as conversational, or pragmatic. This means that the hearer constructs and evaluates a hypothesis about the speaker's meaning. In this process she/he relies on the meaning of utterances, contextual and background assumptions, and general communicative principles that speakers are supposed to observe in normal circumstances. In the center of the Gricean approach are the so-called implicatures which are aspects of the speaker's

meaning inferred on the basis of contextual assumptions of communication and principles.

Out of the three main elements of inferential intention-recognition: meaning of utterances, contextual and background assumptions, and principles of communication, the latter has generated most debate. Pragmaticians have been engaged in searching for communicative principles that govern communication. A principle is the formalized expression of the behavior of a system. It is not a statistical generalization but a causal, mechanical explanation, a general law. Models of communication, especially cognitive ones, have made serious efforts to identify the principles that govern different aspects of use and understanding of language.

Cooperative Principle

Grice regarded cooperation as the ruling element of verbal communicative interaction. He argued that utterances automatically create expectations that guide the hearer toward the speaker's meaning. He considered communication to be both rational and cooperative, and claimed that the inferential intention-recognition is governed by a cooperative principle and maxims of quality, quantity, relation,

and manner (truthfulness, informativeness, relevance and clarity), which speakers are expected to observe (Grice, 1961, 1989: 368–372). The interpretation that a hearer should choose is the one that best satisfies his/her expectations. Inferential communication can be considered successful when the communicator provides evidence of her/his intention to convey a certain thought, and the audience infers this intention from the evidence provided by the communicator.

Grice's inferential approach to communication has been so fundamental that all subsequent pragmatic theories have been influenced by it. Researchers have accepted and relied on the inferential nature of communication, but some have questioned the cooperative principle and maxims as the governing communicative principle of communication. Several critics of the Gricean view (e.g., Keenan, 1979; Traunmüller, 1991) expressed their skepticism about the universality of maxims, arguing that different cultures have different principles or maxims. According to Gumperz (1978), culturally colored interactional styles create culturally determined expectations and interpretive strategies and can lead to breakdowns in intercultural and interethnic communication. Others, such as Sperber and Wilson (1995), argued that cooperation is not essential to communication and suggested a reduction of Grice's maxims to a single principle of relevance. According to this view, a rational speaker will choose an utterance that will provide the hearer with a maximum number of contextual implications in a minimum processing effort. In recent years, two approaches have emerged as most influential in the debate about the communicative principle: the neo-Gricean view and the theory of relevance.

Neo-Gricean View

Neo-Gricean pragmatists such as Horn (1984) and Levinson (2000) retained the view that cooperation is essential to communication. Whether generalized or particularized, they argue, conversational implicature derives from the shared presumption that speaker and hearer are interacting rationally and cooperatively to reach a common goal. Although they kept the cooperative principle as a decisive factor of communication, they revised the maxims to account for a range of generalized implicatures, which Grice described as carried in all normal contexts and contrasted with more context-dependent particularized implicatures. In his book, Levinson addressed the problem of "generalized conversational implicatures (GCI)" as opposed to "particularized conversational implicatures (PCI)." He claimed that only the former are truly linguistic in that only they do not rely on "specific

contextual assumptions" (Levinson, 2000: 16). He emphasized that "... a theory of GCIs has to be supplemented with a theory of PCIs that will have at least as much, and possibly considerably more, importance to a general theory of communication. It is just to a linguistic theory that GCIs have an unparalleled import" (Levinson, 2000: 22). Levinson listed three principles that guide generalized conversational implicatures:

Q-Principle:

Speaker: Choose the maximally informative expression alternative (that still is true).

Addressee: Assume that speaker has chosen the maximally informative expression alternative (that still is true).

I-Principle:

Speaker: Produce only as much linguistic information as necessary to satisfy the communicative purpose.

Addressee: Enrich the given linguistic information, identify the most specific information relative to the communicative purpose.

M-Principle (Modality/Manner/Markedness)

Speaker: Communicate non-normal, non-stereotypical situations by expressions that contrast with those that you would choose for normal, stereotypical situations.

Addressee: If something is communicated by expressions that contrast with those that would be used for normal, stereotypical meanings, then assume that the speaker wants to communicate a non-normal, non-stereotypical meaning.

Relevance Theory

Supporters of Relevance Theory share Grice's intuition that utterances raise expectations of relevance. However, they question several other aspects of his approach, including the need for a cooperative principle and maxims, the focus on pragmatic processes that contribute to implicatures rather than to explicit, truth-conditional content, the role of deliberate maxim violation in utterance interpretation, and the treatment of figurative utterances as deviations from a maxim or convention of truthfulness (Sperber and Wilson, 1995, 2004). Building on the central insights of Grice's contribution but advancing beyond him in significant ways, Sperber and Wilson (1995) argued that cooperation is not crucial for ostensive communication. However, it is fundamental for all speakers to form their contributions so that the audience will not only attend to them but will be able to infer the intended meaning without unjustifiable processing effort. This approach is grounded in a general view of human cognition according to which human cognitive processes are geared to achieving the greatest possible cognitive effect for the smallest possible processing effort. In order for individuals to achieve this, they must focus their attention on what seems to be

the most relevant information available to them. A feature of Sperber and Wilson's theory that is significantly different from Grice's is the idea that the processing of an utterance involves the construction of a context in which the effects of the utterance are evaluated. The context is not given, but is enriched in such a way that the processing of the utterance is facilitated (*See Relevance Theory*).

Sperber and Wilson believe that to communicate verbally is to claim an individual's attention: hence, to communicate is to imply that the information communicated is relevant. This fundamental idea, according to which communicated information comes with a guarantee of relevance, is the communicative principle of relevance. They argued that the principle of relevance is essential to explaining human communication because human cognition tends to be geared to the maximization of relevance (cognitive principle of relevance). According to relevance theory, utterances raise expectations of relevance not because speakers are expected to obey a cooperative principle and maxims or some other specifically communicative convention, but because the search for relevance is a basic feature of human cognition which communicators may utilize (Sperber and Wilson, 2004).

In their book, Sperber and Wilson (1995) demonstrated how these principles are enough on their own to account for the interaction of linguistic meaning and contextual factors in utterance interpretation. Their claim is that the expectations of relevance raised by an utterance are precise enough, and predictable enough, to guide the hearer toward the speaker's meaning. The aim is to explain in cognitively realistic terms what these expectations of relevance amount to and how they might contribute to an empirically plausible account of comprehension.

Criticism of the Principle of Relevance

Levinson (2000) criticized Relevance Theory (RT), while making the case that generalized conversational implicatures comprise a distinct domain within pragmatics. He relies on the Gricean distinction between generalized and particularized conversational implicature and claims that an approach such as RT (Sperber and Wilson, 1995), which does not give any theoretical weight to the distinction and uses the same communicative principle and comprehension procedure in the derivation of all conversational implicatures, cannot really give an adequate account of the nature of these generalized inferences. According to Levinson, RT does not allow for an intermediate level of generalized conversational implicatures in between 'literal meaning' (semantics) and once-off ('nonce') inferences.

Some researchers have described the relevance-theoretic approach to communication as psychological rather than sociological. Mey said that "relevance theory... does not include, let alone focus on, the social dimensions of language" (2001: 89). Talbot (1994: 3525–3526) called relevance theory "an asocial model," pointing out that, within the RT framework, there is no way of discussing any divergence of assumptions according to class, gender, or ethnicity. In her response to this criticism, Sperber and Wilson (1997) argued that sociological aspects are not left out of RT because the theory considers human communication inferential, and it presupposes and exploits an awareness of self and others. Inferential communication is fundamentally social, not just because it is a form of interaction but also because it exploits and enlarges the scope of basic forms of social cognition.

Verbal communication usually conveys much more than is linguistically encoded. Pragmatic theories such as RT take an interest mainly in the enrichment of linguistic meaning, derivation of standard implicatures, and principles governing the process of communication. Sociolinguists are more interested in the ostensive or non-ostensive uses of the act of communication itself to convey claims and attitudes about the social relationship between the interlocutors. Sperber and Wilson accepted that RT largely ignored these issues. They emphasized, however, that this did not mean to deny their importance. They merely felt that, at that stage of the theory development, they could best contribute to the study of human communication by taking it at its most elementary level and abstracting away from these more complex aspects.

Another issue is that communication can hardly be restricted to what people intend to communicate. People usually communicate more than they intend and, according to Mey and Talbot, Sperber and Wilson's model rests on the exclusion of precisely this (Mey and Talbot, 1988: 746). In their rebuttal, Sperber and Wilson (1997) pointed out that the issue is not whether non-ostensive forms of information-transmission exist but whether they should be treated as communication. In RT, it is argued that unintentionally transmitted information is subject merely to general cognitive, rather than specifically communicative, constraints. Consequently, it falls under the first, or cognitive principle of relevance rather than the second, or communicative principle.

Communicative Principle

Mey (1993: 2001) introduced an inclusive term 'Communicative Principle' that basically comprises

both the Cooperative Principle and the Principle of Relevance. He argued as follows:

People talk with the intention to communicate something to somebody; this is the foundation of all linguistic behavior. I call this the Communicative Principle; even though this principle is not mentioned in the pragmatics literature (at least not under this name – a variant, the ‘Principle of Relevance’, will be discussed later in this chapter), it is nevertheless the hidden condition for all human pragmatic activity, and the silently agreed-on premise of our investigation into such activity. (Mey, 2001: 68–69).

According to the Communicative Principle, intention, cooperation and relevance are all responsible for communication action in a concrete context.

Conclusion

In recent years pragmatics has been thriving both in the social and inferential paradigms.

However, only an integrated model that unifies the linguistic, cognitive, and social aspects of communication has considerable hope to be able to account for what is universal and what is culture-specific in human verbal interaction.

Communities of Practice

P Eckert, Stanford University, Stanford, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

The notion ‘community of practice’ was developed by Jean Lave and Etienne Wenger (Lave and Wenger, 1991; Wenger, 2000) as the basis of a social theory of learning. A community of practice is a collection of people who engage on an ongoing basis in some common endeavor: a bowling team, a book club, a friendship group, a crack house, a nuclear family, a church congregation. The construct was brought into sociolinguistics (Eckert and McConnell-Ginet, 1992a, 1992b) as a way of theorizing language and

gender – most particularly, of responsibly connecting broad categories to on-the-ground social and linguistic practice.

The value of the notion to sociolinguistics and linguistic anthropology lies in the fact that it identifies a social grouping not in virtue of shared abstract characteristics (e.g., class, gender) or simple copresence (e.g., neighborhood, workplace), but in virtue of shared practice. In the course of regular joint activity, a community of practice develops ways of doing things, views, values, power relations, ways of talking. And the participants engage with these practices in virtue of their place in the community of practice, and of the place of the community of practice in the larger

social order. The community of practice is thus a rich locus for the study of situated language use, of language change, and of the very process of conventionalization that underlies both.

Two conditions of a community of practice are crucial in the conventionalization of meaning: shared experience over time and a commitment to shared understanding. A community of practice engages people in mutual sense making – about the enterprise they are engaged in, about their respective forms of participation in the enterprise, about their orientation to other communities of practice and to the world around them more generally. Whether this mutual sense making is consensual or conflictual, it is based in a commitment to mutual engagement, and to mutual understanding of that engagement. Participants in a community of practice collaborate in placing themselves as a group with respect to the world around them. This includes the common interpretation of other communities, and of their own practice with respect to those communities, and ultimately the development of a style – including a linguistic style – that embodies these interpretations. Time, meanwhile, allows for greater consistency in this endeavor – for more occasions for the repetition of circumstances, situations, and events. It provides opportunities for joint sense making, and it deepens participants' shared knowledge and sense of predictability. This not only allows meaning to be exercised, but it provides the conditions for setting down convention (Lewis, 1969).

The community of practice offers a different perspective from the traditional focus on the speech community as an explanatory context for linguistic heterogeneity. The speech community perspective views heterogeneity as based in a geographically defined population, and structured by broad and fundamental social categories, particularly class, gender, age, race, and ethnicity. The early survey studies in this tradition (Labov, 1966; Wolfram, 1969; Trudgill, 1974; Macaulay, 1977) provided the backbone of variation studies, mapping broad distributions across large urban communities. What these studies could not provide is the link between broad, abstract patterns and the meanings that speakers are constructing in the concrete situated speech that underlies them. The search for local explanations of linguistic variability has spurred a range of ethnographic studies over the years (Labov, 1963; Gal, 1979; Eckert, 2000), and in recent decades the ethnographic trend has intensified. A major challenge in such studies is to find local settings in which speakers engage the most intensely in making sense of their place in the wider social world, and in which they articulate their linguistic behavior with this sense. The construct 'community of practice' is a way of

locating language use ethnographically so as to create an accountable link between local practice and membership in extralocal and broad categories. What makes a community of practice different from just any group of speakers (e.g., a bunch of kids found hanging out on the street, or a group of undergraduates assembled for an experiment) is not the selection of the speakers so much as the nature of the accountability for this selection. While every community of practice offers a window on the world, the value of this approach relies on the analyst's ability to seek out communities of practice that are particularly salient to the sociolinguistic question being addressed. It is this selection that makes the difference between particularism and a close-up study with far-reaching significance.

Explanation for broad patterns is to be found in speakers' experience, understanding, and linguistic development as they engage in life as members of important overarching categories. A white working-class Italian-American woman does not develop her ways of speaking directly from the larger categories 'working class,' 'Italian-American' and 'female,' but from her day-to-day experience as a person who combines those three (and other) memberships. Her experience will be articulated by her participation in activities and communities of practice that are particular to her place in the social order. It is in these communities of practice that she will develop an identity and the linguistic practices to articulate this identity. Thus communities of practice are fundamental loci for the experience of membership in broader social categories – one might say that it is the grounded locus of the *habitus* (Bourdieu, 1977).

Survey studies show us that working-class speakers lead in the adoption of local phonological change. While one can speculate about the motivations for this early adoption on the basis of general knowledge about class, the actual dynamics of social meaning can only be found through direct examination of working-class linguistic practice. Ethnographic work in suburban Detroit high schools (Eckert, 2000) sought to understand the salience of class in adolescents' day-to-day practice. The study uncovered an opposition between two large communities of practice, the jocks and the burnouts, that constitute class cultures in the context of the high school. The working-class culture of the burnouts and the middle-class culture of the jocks are specifically adolescent, and class consciousness and conflict takes the form of a highlighted social opposition in school and the maximization of resources in constructing this opposition. Linguistic variables, a prime resource, correlated significantly with participation in these communities of practice, rather than with parents'

social class. The jocks' and burnouts' contrasting orientation to such things as school, the urban area, relationships, and the future provided direct explanations for the burnouts' lead in the adoption of new local changes.

Another important aspect of the communities of practice approach is its focus on the fluidity of social space and the diversity of experience. The speech community perspective's focus on demographic categories implies a center and a periphery (Rampton, 1999). The focus on average behavior for categories suggests a 'typical' speaker, erasing the important activity of speakers at the borders of categories. This also produces a static view of the relation between the linguistic and the social, since change tends to come from the borders (Pratt, 1988). Studies of communities of practice, therefore, can capture the interaction between social and linguistic change. Qing Zhang, for example (Zhang, 2001), has captured the role of stylistic practice among the new Beijing 'yuppies' in the development of new dialect features, and Andrew Wong (Wong, 2005) has traced semantic change in the differential use of the term *tongzhi* 'comrade' between the activist and nonactivist gay communities. Mary Bucholtz's study (Bucholtz, 1996) of a group of girls who were fashioning themselves as geeks – a persona normally reserved for males – provided direct observation of girls pushing the envelope of gender in their daily linguistic practice.

A community of practice that is central to many of its participants' identity construction is an important locus for the setting down of joint history, allowing for the complex construction of linguistic styles. Such history also sets the stage for change. Emma Moore's study of teenage girls in northern England (Moore, 2003) traced the gradual split of a group of somewhat rebellious 'populars' as some of them emerged as the tougher 'townies' in their ninth year. In the process, the vernacular speech patterns of the townies intensified in opposition to those of their more conservative friends.

The enterprise of sociolinguistics (and linguistic anthropology) is to relate ways of speaking to ways of participating in the social world. This is not simply a question of discovering how linguistic form correlates with social structure or activity, but of how social meaning comes to be embedded in language. Meaning is made in the course of local social practice (McConnell-Ginet, 1989) and conventionalized on the basis of shared experience and understanding (Lewis, 1969). The importance of the community of practice lies in the recognition that identity is not fixed, that convention does not pre-exist use, and that language use is a continual process of learning.

The community of practice is a prime locus of this process of identity and linguistic construction.

Communities of practice emerge in response to common interest or position, and play an important role in forming their members' participation in, and orientation to, the world around them. It should be clear that the speech community and the community of practice approaches are both necessary and complementary, and that the value of each depends on having the right abstract categories and finding the communities of practice in which those categories are most salient. In other words, the best analytic process would involve feedback between the two approaches.

Computer Literacy

Introduction: Why Computer Literacy?

If literacy (no matter how we interpret this term) has to do with people's capacities for handling 'letters' (Latin: *literae*), then one may ask: What's so peculiar about the computer that we need to define a special concept called 'computer literacy'? After all, people have been using the notion of literacy for ages, and there has never been a need to define a special kind of literacy for a particular tool of writing, such as a chisel, or a brush, or a pen. 'Penmanship' has become a synonym of 'high literacy' (not necessarily exercised by means of a pen), but nobody has ever felt the need to define 'typewriter literacy' in other terms than in number of words per minute: a good ('literate', if you want) typist can do at least 100 wpm without committing too many errors, whereas a beginner or 'illiterate' person only can do 30 or 40, and will have to use a lot of time correcting her or his mistakes.

The difference that makes a difference

The relation of the writer to his or her instrument has of course always been a complicated one. Sometimes this relation has been known to influence the very way people write: the ancient Greek scribes who performed their art in stone didn't bother to drag all their utensils back to the beginning of the line they just had finished; instead, they let the new line begin where the old one had stopped, only one level lower, and thus the script called *boustrophedon* came into being (where the lines alternate in their direction of writing/reading).

Undoubtedly, the invention of wooden, later lead letter type contributed greatly to the dissemination of written literature; however, the effects on the scribe were never a matter of reflection. Later on, the typewriter got naturally to be used for the purposes of office work, while personal letters and literary 'works of art' had to be composed by hand, if they were to be of any value. Even in more practical domains, such as that of journalism, it is a known fact that the famous Count Dalle Torre, late chief editor of the Vatican daily *Osservatore Romano*, forbade the use of typewriters in his offices as late as 1948, so journalists had to write their copy by hand, and then give it to a typist or typesetter.

The interaction between writer and tool changed dramatically with the advent of the computer. Not only is this writing instrument more perfected than any of its predecessors, but in addition it possesses a great number of qualities enabling people to approach their writing tasks in a different way. Accordingly, 'computer literacy' can be defined as: knowing how to exploit the various new uses that the 'computer interface' between humans and letters can be put to. Let's consider some of these uses.

How to use (and not use) a computer

I will not mention the more specialized functions that computer writing has inherited from earlier technologies, merely perfecting, not changing them: book-keeping and accounting (so-called 'spread sheets'), tabulating, making concordances, automated correspondence and other office work (e.g., the 'automatic reminders' one gets from one's credit card company or the local utilities services). The truly revolutionary aspect of computer literacy is in the effect it has on the writing process itself, that which earlier was thought of by some as taboo to any kind of mechanical implementation.

One could say that the truly 'computer literate' is a person who composes his or her literary production directly on the computer, without any interference except from the interface itself. This is a bit like composing directly on the piano, except that the keyboard there normally does not retain what has been played on it. In contrast, the conserving function of the computer is precisely what enables writers to enter into a totally new relationship with their tool. While earlier work, being dependent on the paper medium, had to be meticulously corrected 'in' the text itself, often with great problems of legibility and understanding (scratching or crossing out, 'whiting out', overwriting, writing in between the lines and in the margins, with multiple versions often canceling out one another, or at least making the perhaps better original lines impossible to retrieve), the computer allows the text producer to maintain near-competence independence.

Paper has always been said to be 'patient' in that it did not protest against whatever the author put down on it, suffering great works of art and utterly trivial composition alike to be entered on its impartial surface. In comparison, the patience that the computer exhibits is not only a matter of the tool: it is situated within the computer 'literate', who knows that Pilate's age-old adage *Quod scripsi, scripsi* 'What I have written, I have written' has been rendered null and void by this new medium. Here, it doesn't matter what is written, for everything can always be reformulated, corrected, transformed, and recycled, at the touch of a keystroke or using a few specialized commands. In extreme cases, we even may see the computer generate near-automatic writing (in the sense of the surrealists), with fingers racing across the keyboard and authors failing to realize what's turning them on. Subsequently, the author who checks and goes over the results may often marvel at the 'inventions' that he or she has been guilty of producing, almost without being aware of the process by which they happened.

Perspectives and dangers

While the acquisition of computer literacy as a condition for employment does not create much of a difference as compared with earlier situations (except for the extra cost and training it involves), the use of the computer in creative contexts represents a true breakthrough in the relationship of humans to their work, especially as regards their ways of creative production and reproduction. The interesting question here is not what the computer does to our *hands*, but in

what ways it affects our *mental* ability to shape and reshape, to work out a thought, then abandon it (but not entirely!), and how it allows us to come back to earlier thoughts and scraps of insights that were jotted down in the creative trance, as it were – perhaps recombining these *disiecta membra* with other pieces of thought, all available at the drop of a keystroke. This qualitative change of our relationship with our creative tools is the true computer revolution and it defines 'computer literacy' as being qualitatively different from earlier, more primitive creative and cognitive technologies (see **Cognitive Technology**).

The dangers of the spread of computer literacy are, of course, that any Tom, Dick or Emma who can handle a keyboard may consider themselves to be geniuses of writing, thus offsetting the positive effect of increased literacy by this reduction of the computer tool to an instrument of the inane and mindless. More importantly, though, the danger exists that users, because of the apparent naturalness of their relationship to the computer, start considering themselves as natural extensions of the machine, as human tools.

One frequently hears computer users employ expressions such as: 'The computer is in a bad mood today' or: 'The computer doesn't want to cooperate'; one sees irritated users kick their machines, pound their keyboards, or scream at their screens, accusing them of lack of cooperation. Such expressions (when they are not caused by either the user's poor computer literacy, or by a particular hardware or software deficiency) may reflect either a lack of critical awareness of the computer's properties as an auxiliary tool, or a failure to distinguish between what is the respective role of the partners in human computer interaction and cooperation. As I have shown elsewhere (Gorayska & Mey 1996), the future of human computer interaction lies in the humanizing of the tool, not in the humans' becoming more tool-oriented and tool-like: the computer tail should never be allowed to wag the user dog.

Conspicuity

B Nerlich, University of Nottingham, Nottingham, UK

© 2006 Elsevier Ltd. All rights reserved.

It is normally assumed that for communication to work efficiently, we should avoid the multiplication of meanings. This is supported by Grice's description of the Maxim of Manner, according to which we have to "be perspicuous," and therefore, among other things, "avoid ambiguity" (Grice, 1975) (*see Grice, Herbert Paul; Maxims and Flouting*). However, in ordinary conversations, speakers often put much more into their utterances than is obvious from the surface of the sentence, and hearers generally take out much more than is presented to them on the surface. To understand this multiplication of meaning, another Maxim of Manner should be introduced, according to which we have to "be conspicuous" and therefore "relish ambiguity." This maxim subsumes two general pragmatic principles: "Make your conversation as interesting/witty/surprising as possible" and "Make your utterance/text as expressive as possible, but still accessible." It can be linked to two of Leech's principles of pragmatics, the Interest Principle, which is part of interpersonal rhetoric, and the Expressivity Principle, which is part of textual rhetoric. According to the Interest Principle, we prefer a conversation that is interesting, in the sense of having unpredictability or news value, to a conversation that is predictable (Leech, 1983: 156). It tells you to be witty. Conversations as mere exchanges of information can be boring, whereas conversations that force us to infer more from the utterances than we actually get on the surface are the ones that we love to engage in, provoke, and prolong. Meaning depends on the information people can take out of an utterance, rather than the information that is already in it. What counts is semantic depth on the one hand (the depth of conversational implicatures) (*see Implicature*) and the witty exploitation or creation of multiple meanings on the other. Leech's Expressivity Principle is "concerned with effectiveness in a broad sense which includes expressive and aesthetic aspects of communication, rather than simply with efficiency" (Leech, 1983: 68). Research therefore is needed to answer questions such as: How do people use polysemous words in their daily linguistic interaction? How do they become aware of the existence of multiple

meanings? Do they use them to achieve certain rhetorical, communicational, and social effects? (*see Nerlich and Chamizo Domínguez, 1999; Nerlich and Clarke, 2001*) Normally, the injection with and extraction of a 'surplus' of meaning from utterances (based on established polysemies or on conversational implicatures, or a mixture of both) goes unnoticed, because this surplus is congruent with the surface forms that hint at it and with the context in which they are used. This normal contextual unfolding of that which is implicated (meant) by an utterance used in context, but not 'said,' has been studied in a Gricean framework, using notions such as conversational implicature and speaker meaning vs. sentence meaning (*see Mey, 2001: 43*). There are, however, also cases when the inherent multiplicity of meanings is itself brought to the surface, is exposed in our daily conversational interaction, when we challenge the 'principle of conventionality' through the introduction of incongruity and dissonance. Although Grice implied in his writings that implicatures are an everyday phenomenon, he stressed that ambiguity, irony, and so on are violations of the communicative norm. And yet, it is this 'violation', this 'flouting' of conversational maxims that makes conversations interesting, that makes people actually engage in and enjoy conversations.

Constraint, Pragmatic

K Jaszczolt, University of Cambridge, Cambridge, UK

© 2006 Elsevier Ltd. All rights reserved.

Rules, processes, and representations in pragmatic theory can come with conditions, or restrictions. Such restrictions, or constraints, pertain to the scope of application of a rule, the spread of the process, or the well-formedness of a representation. They can be seen as external restrictions delimiting, for example, an application of a theory, or as an integral part of the theory (*see also* **Pragmatics: Overview and Metapragmatics**).

In optimality-theory pragmatics (e.g., Blutner, 2000; Blutner and Zeevat, 2003), constraints constitute an integral part of the theory (*see* **Pragmatics: Optimality Theory**). Because linguistic meaning underdetermines the proposition expressed, a pragmatic mechanism of completion of this meaning is proposed. It is conceived of as an optimization procedure, founded on the idea of the interaction of violable and ranked constraints. The selected, optimal proposition is the one that best satisfies the constraints. This selection is performed by the pragmatic system whose role is to interpret the semantic representation of a sentence in a given setting. This system is founded on the principles of rational communication worked out by Grice and subsequently by Horn (1984) and Levinson (1987, 2000) in the form of the Q-principles and I/R-principles (*see also* **Implicature; Grice, Herbert Paul; Neo-Gricean Pragmatics; Pragmatics and Semantics**). The I/R-principle compares different interpretations of an expression, while the Q-principle assesses the produced structure as compared with other unrealized possibilities: It blocks interpretations that would be more economically connected with alternative forms. Examples of interpretation constraints are STRENGTH (preference for informationally stronger readings), CONSISTENCY (preference for interpretations that do not conflict with the context), FAITH-INT (faithful interpretation, interpreting all that the speaker said). FAITH-INT precedes CONSISTENCY which precedes STRENGTH in the ranking (*see* Zeevat, 2000).

Another example of constraints that are constitutive of the theory is Segmented Discourse Representation Theory (SDRT) (e.g., Asher and Lascarides, 2003). In SDRT, rhetorical relations spell out constraints on discourse interpretation. The interpretation of discourse is founded on constraints on discourse coherence. For example, a relation between two propositions can be Narration, Explanation, or Elaboration.

Theory-external constraints can be exemplified by particular lexical items that provide certain

restrictions on interpretation. For example, it has been observed by Grice that there are certain words that do not contribute to the truth-conditional content of an expression. Among such words are 'but,' 'moreover,' and 'therefore.' While Grice classified them as conventional implicatures, it was subsequently suggested (Blakemore, 1987) that they do not have conceptual content but instead are indicators of pragmatic inferences to be performed by the addressee. 'After all,' 'you see,' 'also,' and other such indicators also belong to this category:

A: 'Oscar and Lucinda is worth reading. After all, one of the best novelists wrote it.'

'After all' functions here as an indicator that the second sentence is to be taken as evidence for the claim made in the first. By Blakemore's account, such indicators contain procedural (rather than conceptual) meaning and they act as constraints on inference in communication. This approach to constraints on inference has been developed and plays a major role in relevance theory. Blakemore (1987) calls such indicators constraints on the relevance of a proposition. Moreover, it has since been observed (Wilson and Sperber, 1993) that there are also procedural items that constrain the proposition expressed, such as pronouns, as well as markers such as 'please' and 'let's' that constrain the process of inferring the propositional attitude of the speaker or the speech act. The scope of the category of such constraints, as well as the binary conceptual-procedural distinction, still remain a contentious matter (*see, e.g.,* Blakemore, 2002; Lee, 2002) (*see* **Relevance Theory**).

Context and Common Ground

H H Clark, Stanford University, Stanford, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

People talking to each other take much for granted. They assume a common language. They assume shared knowledge of such things as cultural facts, news stories, and local geography. If they know each other, they assume shared knowledge of earlier conversations and other joint experiences. And if they are talking face to face, they assume shared knowledge of the scene around them. 'Common ground' is the sum of the information that people assume they share. Although the notion is often treated informally, it has a formal definition that has been essential to the study of semantics, pragmatics, and other areas of language.

History

'Common knowledge' as a technical notion was introduced by David Lewis (1969) to account for how people coordinate with each other. Suppose A, B, and C agree to meet at city hall at noon. The three of them take it as common knowledge that they intend to go to city hall at noon if and only if: (1) all three believe that the agreement holds; (2) the agreement indicates to all of them that they believe the agreement holds; and (3) the agreement indicates to all of them that they intend to go to city hall at noon. In Lewis's terminology, the agreement is the 'basis' for A, B, and C's common knowledge that they intend to go to city hall at noon. Common knowledge is always a property of a community of people, even though the community may consist of just two people.

The notion of 'common ground' was introduced, in turn, by Robert Stalnaker (1978), based on Lewis's

common knowledge, to account for the way in which information accumulates in conversation:

Roughly speaking, the presuppositions of a speaker are the propositions whose truth he takes for granted as part of the background of the conversation... Presuppositions are what is taken by the speaker to be the **common ground** of the participants in the conversation, what is treated as their **common knowledge** or **mutual knowledge** [p. 320, Stalnaker's emphases].

In this view, people in conversation take certain propositions to be common ground, and when they make assertions, they add to this common ground. When A tells B, *George arrived home yesterday*, A takes it as common ground with B who George is, what day it is, and where George lives. A uses the assertion to add to their common ground the proposition that George arrived home the day before. Common ground therefore also includes common (or mutual) beliefs, and common (or mutual) suppositions (Clark and Marshall, 1981; Clark, 1996).

Common ground is a reflexive, or self-referring, notion (Cohen, 1978). If A takes a proposition as common ground with B, then A takes the following statement to be true: A and B have information that the proposition is true **and that this entire statement is true**. (*This sentence has five words* is reflexive in the sense that **this sentence** refers to the sentence that contains it.) Because of the self-reference, people can, technically, draw an infinity of inferences from what they take to be common ground. Suppose A takes it that A and B mutually believe that George is home. A can infer that B believes that George is home, that B believes that A believes that George is home, that B believes that A believes that B believes that George is home, and so on *ad infinitum*. In practice, people never draw more than a few of these inferences. These iterated propositions

are therefore a derivative and incomplete representation of common ground. The reflexive notion is more basic (Lewis, 1969; Clark and Marshall, 1981; Clark, 1996).

Bases for Common Ground

In conversation and other joint activities, people have to assess and reassess their common ground, and to do that, they need the right bases. These bases fall into two main categories: community membership and personal experiences (Clark, 1996).

Communal Common Ground

Common ground is information that is common to a community of people. Some of these communities are built around shared practices or expertise, such as the communities of ophthalmologists, New Zealanders, or English speakers. Once A and B mutually establish that they are both ophthalmologists, New Zealanders, or English speakers, they can take as common ground everything that is taken for granted in these communities. Even if A and B mutually establish that A is a New Zealander and B is not, they can take as common ground everything an outsider would think an insider should know about New Zealand. Common ground based on community membership is called ‘communal common ground.’

Everybody belongs to many communities at the same time. Some of these communities are nested (e.g., North Americans, Americans, Californians, San Franciscans, Nob Hill residents), and others are cross cutting (Californians, lawyers, football fans, Christians). Both nesting and cross-cutting communities lead to gradations in common ground. Any two Californians might readily presuppose common knowledge of the Golden Gate Bridge on San Francisco Bay, but only two San Franciscans would presuppose common knowledge of Crissy Field right next to it.

People have both direct and indirect ways of establishing which communities they jointly belong to. When people meet for the first time, they often begin by exchanging information about their occupations, residences, hobbies, and other identities. They display other communal identities indirectly – in their choice of language, dialect, and vocabulary; their choice of dress and accoutrements; and their age and gender. It is remarkable how many cultural identities people can infer as they talk and how useful these are in establishing communal common ground.

Personal Common Ground

The other main basis for common ground is joint experience. The joint experience may be perceptual.

When A and B look at a candle together, they can take their joint experience as a basis for certain mutual beliefs – that there is a candle between them, that it is green, that it smells of bayberry, that it is lit. Or the joint experience may be linguistic or communicative. When A tells B (on April 8), *George arrived home yesterday*, and once they mutually establish that B has understood A, the two of them can take it as common ground that George arrived home on April 7. Common ground that is based on joint perceptual or linguistic experiences between two people is called their ‘personal common ground’. It often holds only for the two of them.

Conversations and other joint activities depend on the orderly accumulation of personal common ground. Suppose A and B are assembling a television stand together. To succeed, they need to establish as common ground what each is going to do next. Part of this they accomplish linguistically, in their spoken exchanges, as when A proposes, *Let’s put on this piece next*, and B takes up the proposal, *Okay*. But other parts they accomplish perceptually, as when A hands B a board, screw, or screwdriver, or when A holds up a board and they examine it together. Most face-to-face conversations depend on a mix of linguistic and perceptual bases for the accumulation of personal common ground. Telephone conversations depend almost entirely on linguistic bases.

Language and Communal Common Ground

Communal common ground is fundamental to account for the conventions of language, what are termed the ‘rules of language’. These include conventions of semantics, syntax, morphology, phonology, and pragmatics (Lewis, 1969).

Speakers ordinarily try to use words that their addressees will understand, and that requires a ‘shared lexicon.’ The problem is that every community has its own ‘communal lexicon’ (Clark, 1996). Once A and B jointly establish that they are both speakers of English, they may presuppose common knowledge of a general English-language lexicon. But because other communities are nested and cross cutting, so are the lexicons associated with them. There is a nesting of communities that speak English, North American English, New England English, and Bostonian. Although words such as *dog* and *in* are common to English in general, others are common only to one or another nested community; in Bostonian, for example, a *barnie* is a Harvard student. Indeed, every community (Californians, lawyers, football fans, ophthalmologists) has a specialized lexicon. The lexicon for lawyers includes *tort*, *mortmain*, and

ne exeat. The lexicon for ophthalmologists includes *tonometry*, *uveal*, and *amblyopia*. To use *barnie* or *mortmain* is to take as common ground a Bostonian or legal lexicon. Communal lexicons are sometimes called jargon, dialect, patois, idiom, parlance, nomenclature, slang, argot, lingo, cant, or vernacular; or they consist of regionalisms, colloquialisms, localisms, or technical terminology.

Speakers also try to use syntactic constructions, or rules, that they share with their addressees. For example, in English generally, it is conventional to mention place before time (*George is going to London tomorrow*); yet in Dutch, a closely related language, it is conventional to mention place and time in the reverse order (*Pim gaat morgen naar London*, 'Pim goes tomorrow to London'). The rules of syntax, however, vary by nested communities. It is conventional to say *He gave it me* in British English, but not in English generally. It is conventional to say *My car needs washed* in Western Pennsylvania English, but not in North American English. Many rules of syntax are tied to specific words in a communal lexicon, and these vary from one community to the next.

Speakers also try to use, or adapt to, the phonology of their cultural communities. Indeed, pronunciations vary enormously from one community to the next. The vowel in *can't*, for example, changes as one goes from British to North American English, from northern to southern dialects of American English, and even from one social group to another within a single school. Also, the same person may pronounce *singing* as 'singin' in an informal setting but as 'singing' in a classroom or a court of law.

Discourse and Personal Common Ground

Personal common ground is essential to the processes by which people converse. To *communicate* is, according to its Latin roots, to *make common* – to establish something as common ground. To succeed in conversation, people must design what they say (1) against the common ground they believe they already share with their interlocutors and (2) as a way of adding to that common ground (Stalnaker, 1978). Two consequences of trying to make something common are 'information structure' and 'grounding.' 'Information structure' is a property of utterances. When A tells B, *What the committee is after is somebody at the White House*, A uses the special construction to distinguish two types of information (Prince, 1978). With the Wh-cleft *What the committee is after*, A provides information that A assumes B is already thinking about. It is one type of 'given information.' In contrast, with the remainder of the utterance 'is somebody at the White

House,' A provides information that A assumes B doesn't yet know. It is 'new information.' Given information is assumed to be inferable from A and B's current common ground, whereas new information is not. New information is, instead, what is to be **added** to common ground. The way people refer to an object in a discourse (e.g., the committee, somebody, of the White House) depends on whether they believe that the object is readily evoked, known but unused, inferable, or brand new in their common ground for that discourse (Prince, 1981).

'Grounding' is the process of trying to establish what is said as common ground (Clark and Schaefer, 1989; Clark and Brennan, 1991). When A speaks to B in conversation, it is ordinarily not enough for A simply to produce an utterance for B. The two of them try to establish as common ground that B has understood what A meant by it well enough for current purposes. In this process, B is expected to give A periodic evidence of the state of his or her understanding, and A is expected to look for and evaluate that evidence. One way B can signal understanding is with back-channel signals such as *uh-huh*, *yeah*, a head nod, or a smile. Another way is with the appropriate next contribution, as when B answers a question asked by A. But if B does not manage to attend to, hear, or understand A's utterance completely, the two of them will try to repair the problem. One way is illustrated here:

A (on telephone): Can I speak to Jim Johnstone, please?

B: Senior?

A: Yes.

B: Yes.

In turn 2, B asks A to clear up an ambiguous reference in A's question, and in turn 3, A does just that. Only then does B go on to answer A's question. Turns 2 and 3 are called a 'side sequence' (Jefferson, 1972). Grounding takes many other forms as well.

Common ground is central to accounts of language and language use. It is needed in accounting for the conventions, or rules, of language and to explain how people contribute to conversation and to other forms of discourse.

Introduction

One of the central foci of research on language over the last several decades has been the relation between language and context. Work in linguistic anthropology, sociolinguistics, pragmatics, psycholinguistics, and philosophy of language has demonstrated a wide variety of ways in which language and verbally communicated information of various sorts are informed and even shaped by the social and interpersonal contexts in which speech occurs (see Duranti and Goodwin, 1992). Overlapping lines of research have also demonstrated various ways in which language constitutes context, including the social effects described in speech act theory (see **Speech Acts**), the formulation and attribution of beliefs in relevance theory (Grice, 1989; Levinson, 2000; Sperber and Wilson, 1995) (see **Relevance Theory**) and the 'creative use' of indexical terms such as pronouns, deictics, and other shifters (Silverstein, 1976) (see **Indexicality: Theory**). The focus on context, as both a constraining factor and a product of discourse, has led to increasingly fine-grained approaches to speech, since it is primarily in the formation of spoken or written utterances that language and context are articulated. The significance of these developments for linguistics lies in the increased precision with which linguistic systems, cognitive processes, and language use are articulated. For anthropology, it lies primarily in the fact that communicative practice is integral to social practice more generally. Language is a factor, if not

a defining one, in most of social life, and ideas about language have had a basic impact on social theory for the last century.

Given the scope of these developments, it is unsurprising that there are various approaches to context corresponding to the disciplinary predilections of researchers. Speech act theory zeroed in on the relation between speech forms and circumstances as captured in felicity conditions and the doctrine of (illocutionary) force (Austin, 1962). Gricean approaches to conversation focus on inference and belief ascription under the assumption that speech is a cooperative engagement, subject to the maxims of quality, quantity, relation, and manner (Grice, 1989) (see **Maxims and Flouting**). Relevance theory shares a focus on inference as a central feature of speech, but dispenses with the Gricean cooperative principle (see **Cooperative Principle**), maxims, and the tasks of calculating and testing for implicatures (see **Implicature**). In their place, it proposes to explain inferential processes in terms of a single principle of relevance according to which logical, encyclopedic, and lexical information are combined. Speech act, implicature, and relevance theories are all closely associated with linguistics and have in common that they treat context as built up utterance by utterance in the course of speaking.

From a social perspective, ethnomethodology and conversation analysis have made major contributions to our understanding of language in interaction (see **Conversation Analysis**). Both assert that face-to-face interaction is the primordial context for human sociality (Schegloff, 1987: 208) and the most important locus of observation of language. While they may rely on the pragmatic and inferential processes studied by linguists, their focus is different.

Conversation analysis (CA) has emphasized the temporal and hence sequential organization of verbal exchange (Sacks *et al.*, 1974), the existence of procedural rules guiding turn taking in talk, the phenomenon of conversational repair, and the micro-analysis of actually occurring verbal interaction (*see Conversation Analysis*). Psycholinguists and cognitive linguists treat context as a matter of mutual knowledge and cognitive representation, hence as a basically mental construct.

The approaches mentioned so far have in common that they treat context as a radial structure whose center point is the spoken utterance. They share a commitment to methodological individualism, which prioritizes the individual over the collective and seeks to reduce social structures to individual behaviors. Starting from the perspective of the participant(s) in speech production, they derive context from relevance, mental representation (including attention focus and practical reason), and the momentary emergence of the speech situation. From this viewpoint, context is a local concomitant of talk and interaction, ephemeral and centered on the emergent process of speaking. Whether one places primary emphasis on actual language use as attested in the field or on constructed examples, the ultimate frame of reference and explanation is individual speech activities and the verbal interactions in which they occur.

From the opposite viewpoint, others have developed approaches to language and discourse in which context is neither local nor ephemeral, but global and durable, with greater social and historical scope than any localized act. There are several shifts here worth distinguishing. Whereas the first set of approaches is grounded in linguistics, psychology, and microsociology, the second is based in large-scale social theory and history. Utterance production is not assumed to be the generative center of context, as it is for individualist approaches. Rather, the explanatory frameworks are social and historical conditions that are prior to discourse production and place constraints on it. Standard linguistic description is a case in point, because it claims that individual uses of language depend for their intelligibility on linguistic systems (grammatical and semantic) that are logically prior to any act of speech. To the extent that such perspectives treat discourse production at all, the relevant units are either analytic abstractions (the idealized Speaker of linguistics) or collectivities (communities, classes, social networks, kinds of agent defined by gender, age, profession, residence, etc.). Similarly, the temporal frame of discourse production is not the momentary unfolding of utterances in what individualists call real time, but the conjunctural time of collective systems and historical processes.

Just as there are various local approaches to context, there are also diverse global ones. In a Foucaultian view, for example, if there can be said to be a basic context for language, it is neither interaction nor the individual strips of speech or text familiar to linguists. On the contrary, the frame of reference is 'discourse,' meaning large-scale formations of beliefs and categorizations pervaded by power relations and articulated in 'assemblages.' (*see Discourse, Foucauldian Approach; Power and Pragmatics*). Similarly, Bourdieu has argued that language forms and varieties should be analyzed relative to linguistic markets in which they bear various sorts of symbolic and cultural capital (Bourdieu, 1993). Both Foucault and Bourdieu take as their point of departure collective facts and set out views contradictory to methodological individualism (a predictable corollary of the structuralist orientation of both thinkers). Critical discourse analysis (CDA) offers another clear example (nicely reviewed in Blommaert and Bulcaen, 2000). In this approach, discourse is treated under three perspectives: as text endowed with linguistic form, as 'discursive practice' through which texts are produced, distributed, and consumed and as 'social practice' which has various ideological effects, including normativity and hegemony. CDA emphasizes power, exploitation, and inequality as the social conditions of language, tracing them through various contexts including political and economic discourse, racism, advertising and media, and institutional settings such as bureaucracies and education. Notice that, while these forces may be played out in individual speech events, the frame of reference is broader than, and logically prior to, any given event. Moreover, the focus on speakers' intentions as the source of meaning that is common to methodological individualist approaches is absent in all large-scale approaches (*see Critical Discourse Analysis*).

The linguistic, psychological, and microsociological approaches from which we started are largely complementary to the large-scale approaches just mentioned. The local settings of utterance and face-to-face interaction that are central to the first group are absent or at best marginal in the second. Conversely, the collective facts central to social definitions of context are marginal or simply ignored in individualist approaches. This polarization gives rise to overstatement and many missed opportunities for productive research. It becomes unclear how to articulate different levels of context analytically, or even whether such articulation is an appropriate aim. Given that discourse responds to context at multiple scales, and that any actual social setting can be characterized under either micro- or macro-perspectives, the two are inevitably pitted against one another.

In its strong forms, methodological individualism claims that the collective facts studied by sociologists and anthropologists are epiphenomena of individual actions, whereas a proponent of collectivism may claim with equal conviction that individual utterances and face-to-face interactions are the trivial precipitates of larger social forces. Thus, the dichotomies of scale underwrite contradictory claims about what is most basic to context.

While much of the literature bearing on context can be placed on one or the other of these extremes, linguistic anthropology has been the exception because it has attempted to integrate levels (see **Linguistic Anthropology**). One motivation for this is the empirical fact that speech practices are shaped by and help shape contexts at various levels. Another is the patent inadequacy of all bipolar accounts, which inevitably distort the relative significance of contextual features and produce a vacuum at one level or the other. As an interdisciplinary enterprise, linguistic anthropology has always straddled grammar and actual language use in socially and historically defined settings. The focus on speech requires detailed analysis of locally emergent facts both linguistic and ethnographic (hence 'micro'), while the focus on linguistic and social-cultural systems requires equally careful analysis of formal and functional regularities whose motivations lie far beyond individuals and their actions (hence 'macro'). Thus, the ethnography of speaking combined such descriptive units as the speech event, the community, and verbal repertoires in an attempt to bring the ethnographic setting of utterances to bear on their formal and functional properties. In recent decades, linguistic anthropologists examined the relation between language and political economy and what has come to be known as language ideologies, both of which combine phenomena from different scales (Silverstein, 1979; Schieffelin *et al.*, 1998). Any study of context that seeks to account for the formal specificity of utterance practices and their social embedding must reject familiar divisions between micro- and macrolevel phenomena.

Context is a theoretical concept, strictly based on relations. There is no 'context' that is not 'context of,' or 'context for.' How one treats it depends on how one construes other basic elements including language, discourse, utterance production and reception, social practice, and so on. It is by now widely recognized that much (if not all) of the meaning production that takes place through language depends fundamentally on context and further, that there is no single definition of how much or what sorts of context are required for language description. There is therefore no reason to expect that any single model or set of processes will be analytically sufficient for

all research (and good reason to be skeptical of universal claims). At the same time, it is clear that there are principles and kinds of relations that recurrently organize contexts. We are concerned here with both the semiotic specificity of discourse practices and their social and historical embedding. What are the units and levels of context one needs to distinguish in order to give a rigorous account of language as practice? What are the relations and processes that give rise to different contextual units and levels? How does one analyze actual contexts without falling into a morass of particulars?

My way into these questions is through two broad dimensions of context, which I will call emergence and embedding. The former designates aspects of discourse that arise from production and reception as ongoing processes. It pertains to verbally mediated activity, interaction, copresence, temporality, in short context as a phenomenal, social, and historical actuality. Embedding designates the relation between contextual aspects that pertain to the framing of discourse, its centering or groundedness in broader frameworks. So stated, there is an initial alignment of emergence with the highly local sphere of utterance production, on the one hand, and embedding with larger scale contexts on the other. This is the way the two are usually discussed in the literature on language. Emergence is associated with so-called real time utterance production and interaction, and embedding describes the locatedness of utterances in some broader context. However, emergence can easily be conceived at different temporal levels, as any historian knows, just as embedding applies within the most local fields of utterance production. To see this, let us turn to a more detailed look at each of the dimensions, starting with emergence.

Emergence

Context as a Sheer Situation

In an interesting discussion of the micro-macro problem from the viewpoint of conversation analysis, Schegloff (1987: 208) asserted that interaction, minimally involving two people, is the primordial site of sociality. This view is rooted in a significant history of thought about both sociality and interaction (Schutz, 1970a). The former term is seldom defined precisely, but in Schegloff's pithy claim, it stood for the human propensity to engage with others, with the invited inference that this propensity is a basic aspect of human society. The primordial importance accorded interaction can be traced to the phenomenological sociology of Alfred Schutz. Schutz set about to merge the social theory of Max Weber with the phenomenology of Edmund

Husserl (with a healthy dose of William James and Gestalt psychology). In his view, social subjects develop in a world of intersubjective relationships, in which others are given to them both as objects in space and as other selves (Schutz, 1970a: 163). They partake of a primitive reciprocity in the sense that each exists in relation with the other. They are parties to a mutual 'we,' each located in a world also occupied by the other. In interaction relationships (as opposed to relations among contemporaries or predecessors), the parties are copresent corporeally, which entails their being in the same place at the same time and in what phenomenologists call the 'natural attitude' (wide awake, in their senses, with access to common sense). For each party to interaction, the other's bodily gestures (including utterances) present themselves as expressions that project and make perceptible inner states of consciousness. In interaction, the other's body is primarily a field of expression presumed to be meaningful, not a mere object perceived (*see Gestures, Pragmatic Aspects*). As a corollary of copresence, the two are in the same temporal stream, and each can perceive the other's expressions as they emerge from moment to moment. The mutual copresence and reciprocal access of interactants takes the shape of a more exacting reciprocity: until further notice and for all practical purposes, each party can put himself in the shoes of the other, taking on, or at least entertaining, the other's perspective.

Goffman (1972) helped formulate a Schutzian view of context in his influential paper "The neglected situation" (*see Goffman, Erving*). Goffman critiqued the then widespread treatments of social context in terms of correlations between macrolevel sociological variables, such as gender, class, profession, and institutional roles. He argued that situations have their own properties that follow from the fact of copresence between two or more people. A situation is a space of mutual monitoring possibilities within which all copresent individuals have sensory access to one another with the naked senses. Hence, the following conditions apply:

1. There are at least two parties who cooccupy the same objective time (which Schutz [1970a: 165ff.] distinguished from inner time and the constituted experience of space-time), in which perceptions and expressive gestures unfold sequentially.
2. Each party to the situation is present in body, both perceivable and capable of perceiving the other.
3. The situation is a field of mutual monitoring possibilities, which entails the capacity of the co-occupants to notice and attend to each other.

These three conditions imply mutuality (we share this), cooccupancy of the same space-time (we are

both here-now) and reciprocity (I perceive you and you perceive me). Notice that a situation is not a field of **actual** mutuality, reciprocity, and cooccupancy, but a field in which these are alive as **potentials**. (This is another factor reminiscent of phenomenology in the idea of the 'horizon'). It is minimally structured, logically prior to any utterance, and notably lacking any object beyond the copresent parties. From the perspective of language, the situation provides a sort of 'prior outside' into which speech and language are projected through utterance acts.

Given what we have said so far, all of dialogic speech could be described as situated insofar as it occurs in situations. The utterance *the curry is done* is situated, let's say, when produced by a cook in response to the question *when will dinner be ready?* Both question and response are situated in the perceptible, interactive relationship between the parties, and all three of the above conditions apply. But Goffman distinguished between "merely situated" and inherently situated factors. The former include linguistic and symbolic structures that are instantiated in utterances but do not really depend on the situation for their definition. In contrast, timing and delivery of utterances reflect the *in situ* mutual adjustments between interlocutors and are inherently situated. Goffman's situation, then, represents a layer of context that is prior to language, but with which we can distinguish between merely and inherently situated aspects of the speech stream. A great deal of research over the last decades has demonstrated the significance of this framework, and the ways in which speech transforms and adapts to situations. It has become an article of common sense that context is situated, whatever else it is.

Relevant Settings

The situation thus defined is insufficient to describe interaction because it lacks several basic features. Whereas any situation exists in time, it lacks such temporally grounded distinctions as early vs. late and middle vs. beginning or ending. The latter terms can only be applied to a course of activities in which there are act units and expectations. Furthermore, at the level of the situation each party is potentially aware of the presence of the other, but is not attending to the expressive meaning of the other's gestures. As a mere field of copresence (what Schutz [1970b] called a 'pure we relationship'), a situation has no meaningful structure: nothing in particular is going on or is especially relevant. If we layer onto the situation socially identifiable acts, expectations, mutual understanding among parties, and a framework of relevance, we arrive at a contextual unit closer to interaction and

considerably more structured. We will call this new unit the *setting* (Sacks, 1992: 521–522).

If a speaker says, *I am here to meet with Martin, this is a great party*, or *I'm asking you to help* (s)he has in each case **formulated** the setting in which the utterance occurs. In the language of CA, a formulation is a description, hence a categorization, as opposed to indexical expressions that invoke the setting, but do not formulate it since they lack descriptive content. In paradigm cases, the formulation applies reflexively to the very speech setting in which it occurs. What most concerns us at this point is that formulations are internal to interactive context, they display the participants' judgments of what is relevant and going on, and they illustrate the conversion of a mere situation into a social setting (Schegloff, 1987).

To introduce the concept of relevance is to transform fundamentally the idea of context. On the one hand, judgments of relevance always imply a theme or point of interest from which the relevance relation is established. On the other hand, this relation is rooted in actors' previous experiences, in light of which the interest arises (Schutz, 1970b: 5). A theme, like a focal point, implies a background or horizon against which it is distinguished and in relation to which it functions as a center point. This in turn implies that any context in which thematic relevance operates is a bilevel structure (usually described as foreground/background, or theme/horizon). The reference to the biographical history of the actors for whom something is thematic effectively expands the temporal scope of context from the vivid present of situated perception to a past remembered and sedimented through habitual experience. In short, as soon as we introduce relevance, context becomes a hierarchical structure connected to a nonlocal history.

In addition to the distinction between theme and horizon, Schutz (1970b) developed a three-way contrast between kinds of relevance, which he calls topical, interpretive, and motivational. The first centers on the object or matter to which actors turn their attention. The second has to do with which aspects of the object are relevant to the question at hand, and which parts of the actor's background knowledge are brought to bear on it. The third pertains to the actor's prospective purpose (which Schutz called "in order to motives") and the past conditions that give rise to that purpose (Schutz's "because motives"). The combined effect of these three sorts of relevance is to create a multistranded relevance system in the setting, encompassing both memory and anticipation. While Schutz's probing study makes further distinctions, these will suffice to underscore that interactive context, even at the relatively primitive level of the

setting, is hierarchical along several dimensions, both local copresent and nonlocal.

Semiotic Field, Symbolic and Demonstrative

Although we introduced the function of formulation in order to clarify the difference between a situation and a setting, our framework is as yet impoverished from the perspective of language structure and semiotics. This is the next element we must introduce in order to approximate a notion of context adequate for linguistic description. We will do so by way of the theory developed by Karl Bühler (1990 [1934]), which had a profound impact on subsequent linguistic and semiotic approaches to context (particularly the ethnography of speaking, linguistic treatments of deixis and contemporary linguistic anthropology). Bühler distinguished two aspects of the context in which any sign is used: (i) the *Symbolfeld* 'symbolic field,' consisting of words, other signs, and the concepts they represent, and (ii) the *Zeigfeld* 'demonstrative field,' which is the immediate interpersonal setting in which an utterance is produced. These two elements combine in various ways in Bühler's treatment, for instance anaphora and "imaginary deixis," (see Bühler, Karl; **Deixis and Anaphora: Pragmatic Approaches**) and the resulting model of context is pervasively semiotic. It inherits all the features of settings as laid out above, but these are transformed by signs (symbolic, indexical, iconic), sign relations (syntactic, semantic, pragmatic), the presence of objects stood for, and various functions including individuated reference and directivity (purposive orientation of an interlocutor's attention by word and gesture).

Bühler summarized the *Zeigfeld* as "Here Now I," thus foregrounding its relation to the linguistic system(s) of the participants. These three terms are the prototypical deictics: they are referring expressions whose conventional meanings belong to the linguistic code, and yet, as indexicals, their reference on any occasion of use depends strictly on the context of utterance. Deixis is the single most obvious way in which context is embedded in the very categories of human languages. Recall that in Sacks' terms, deictics 'invoke' the setting, because they are indexicals, but do not 'formulate' it, because they lack descriptive content. Contrast *I am here* with *I am in the dining room of my home*. It has also become common in the literature to distinguish between referential indexicals, (e.g., deictics, pronouns, presentatives, certain temporal adverbs) and nonreferential or social indexicality (Silverstein, 1976). The latter would include such phenomena as regional or other recognized accents, stylistic registers, and honorifics (Agha, 1998; Errington, 1988) insofar as these

features of language signal aspects of utterance context without actually referring to or describing it. Contrast an utterance spoken with a heavy New England accent, which nonreferentially indexes the provenience of the speaker, with *I am from New England*, which states it. What is most relevant about indexicality for present purposes is the way that both referential and nonreferential varieties serve to articulate language as a general system with utterance context. The deictic categories of any language, and the combination of those categories into phrases, sentences, and utterances, reveal schematic templates for context.

The demonstrative field therefore converts the interactive setting into a field of signs. For Bühler, it includes gestures and other perceptible aspects of the participants, such as posture, pointing, directed gaze, and the sound of the speaker's voice, all of which orient the subjective attention focus of the participants. Like Goffman and the conversation analysts, Bühler assumes that the participants are in the "natural attitude": wide awake, oriented, each with a sense of his or her own body, synthesizing sensory data from vision, hearing, and touch in a system of coordinates whose origo is the here-now-I (Bühler 1990: 169ff.). Within this phenomenal setting, utterances, in both their symbolic and indexical dimensions, both reflect and transform context. They orient participants attention, thematize objects of reference, formulate, invoke, and construe the setting, operate on relevance systems, in short, they produce context.

The situation, setting, and demonstrative field are emergent in the sense that they unfold in time. This is one consequence of the fact that linguistic practice produces context in an ongoing fashion. It gives rise to duration, sequence, simultaneity, synchronization, and it forces us to include memory, anticipation, and teleology in our model of context. Time is central to the study of conversation and sequence is basic to turn-taking systems, anaphora, and thematic coherence, the interactive production of sentences (Goodwin and Goodwin, 1992), and the organization of a host of conversational structures. It is also at the root of the concept of adjacency in conversation analysis, the relation between contiguous units in talk.

Notice that emergence entails time but is different from it, since it describes the relation between various units of discourse production. When individuals co-engage in a setting, their perceptual fields are oriented by relevance and when they coparticipate in a demonstrative field, they are reoriented by signs. So too temporal relations are converted in the passage from situation to setting to demonstrative field. Diachrony is an existential condition of context at any level of analysis, but it denotes different processes according to the level. For example, the inner duration of

experience, the simultaneity of pure we relations, the production of utterances, the taking of turns at talk, the opening, middle, and closing of conversational units, and the prospective projection implied by intention and strategy are different diachronies. Emergence is everywhere in relation to structure, and to describe context as emergent implies that it is structured.

Embedding

The progression from situation to setting to demonstrative field is neither a temporal sequence nor a set of inclusion relations. It is a matter of logical ordering, from the relatively primitive level of the sphere of perceptual awareness through the semiotically entangled demonstrative field. The setting inherits features of copresence from the *situation*, transforming it by way of relevance relations and socially recognized units of action. The symbolic-demonstrative field inherits an interspectival relevance system from the setting, but transforms it by means of multifunctional semiotic systems (most notably language). The model of context implicit in the demonstrative field is the minimal starting point for the study of discourse.

Whatever else is true about discourse context then, it entails bodies and perceptual fields, relevance systems, act types, and the expectations they engender, semiotic systems and the transformations they effect. As emphasized above, all of these contextual formations are emergent in that they involve duration, sequence, simultaneity and, in the more complex formations, memory and anticipation. In virtually all of ordinary communicative practice, the three levels combine and the distinctions between them are analytic: a setting is merely what is left when we analytically peel away the effects of semiosis; a situation is what remains when we bracket off relevance. Such analytic separation has the advantage of clarifying how discourse contexts hang together and fall apart, and how language and discourse differentially tie into the distinct orders of context. It should not suggest that the three lead separate lives, as it were: in the course of social life, there is no situation that is not tied into a setting and no setting that is cut loose from semiosis. This relation of ordered entailment and tying in we will describe as embedding.

To study context is to study embedding. If contextual formation X is embedded in Y, then the following statements are true:

- i. Y entails X, but X does not entail Y;
- ii. Y inherits certain properties from X but introduces other properties;

- iii. Y transforms X, altering inherited properties and introducing new principles of organization (via rearrangement, reweighting, etc.);
- iv. If any part of X becomes a thematic focus, either for participants or for analysts, then Y is the relevant horizon.

For example, a setting entails the possibility of mutual monitoring among participants, but a situation does not entail a relevance structure (i). The symbolic–demonstrative field inherits act units and relevance relations from the setting, but reconstitutes it via multifunctional semiosis (ii). The relevance system of a setting organizes how participants monitor one another in the situation, and the semiotic functions of the symbolic–demonstrative field transform relevance via thematization (iii). If a problem arises in mutual monitoring among copresent participants, then it is dealt with in light of the setting, which establishes the expectations and relevance requisite to identifying or rectifying the problem. Similarly, if a problem of (ir)relevance or failed expectations arises, then it is grasped and dealt with in the light of the ongoing symbolic–demonstrative field, which invokes, formulates, and provides the means to construe the setting (iv). The upshot of these remarks is that contextual embedding is never a mere add-on or external surround to features of discourse or interaction. At whatever level we examine it, context is embedding relations.

Research in linguistic anthropology over recent decades provides abundant and forceful evidence that embedding is not limited to the contextual levels so far adduced. No symbolic–demonstrative field exists in a social vacuum and however strong the impulse to generalize by way of rules, invariant structures, or procedures, contexts vary more radically than so far suggested, and on parameters not yet mentioned. This comes as no surprise to ethnographers, but it poses a real challenge to linguists because linguistic systems and practices articulate precisely and in detail with social phenomena beyond the reach of even the most sophisticated semiotics. How are we to explain the impact on context of such systematic phenomena as the difference between expert and novice practice in institutional settings (Cicourel, 2001), the role of ideology on discursive practice, the differential affects of national, ethnic, or class identities on discourse production, the values that attach to different ways of speaking, writing, or other mediated forms of discourse that do not assume the face-to-face situation at the heart of the demonstrative field? For example, it is clear that persons and objects in the demonstrative field have, for the participants, values of various kinds. They are good, bad,

beautiful, ugly, mine, yours, costly or cheap, coveted or to be avoided, yet such values derive from social systems and experiences beyond the scope of the demonstrative field. In actual practice, as opposed to theory-driven proxies of practice, discourse circulates in contexts that are themselves embedded in social formations only partly explainable by discourse. In Bühler's demonstrative field, participants and objects are anonymous, the accidental occupants of semiotically defined positions and roles. Yet in ordinary discourse, actual persons, groups, objects, and settings are in play, and these are, for the most part, familiar and valued.

This is one of the most difficult problems in the study of context: in order to achieve a general account, we formulate schematic regularities, yet in order to actually engage in discourse, speakers and addressees must come to grips with emergent particulars. Semiotic accounts seek to overcome this difficulty by distinguishing types (generalities) from tokens (particular instances), or by combining structures (e.g., linguistic systems) with phenomenology (Bühler's solution). The problem with these approaches is that they treat actual practices as merely situated instantiations of general laws, which domesticates particularity by making it a mere instance of the general. At the same time, they preserve a radial definition of context, according to which the individual, utterance, or situation is the center point and all other factors are defined in relation to it. This is a productive solution to certain problems, such as the semantics of indexical reference, where the sign stands for its object in an aboutness relation. But what of an organizational context like a hospital, a university campus, or a courtroom? Most of the interactions that occur in these contexts are shaped in part by institutional frameworks, credentialing processes, and social divisions that exist before and beyond any demonstrative field, that may be nowhere signaled in the discourse, and yet shape the context and constrain participants' access to discourse. We need a way of analyzing contextual dimensions that are not radial to the utterance or the field of copresence, but that shape it significantly. Relegating such factors to the social setting is a convenient shorthand, but it fails to explain how they impinge on discourse. To require that they be relevant to the participants is to require that they be thematized, whereas much of the social formation impinging on discourse contexts is unnoticed. To label them background knowledge begs the question, since most individuals in institutional settings have fragmentary or systematically skewed knowledge of the forces that objectively shape the contexts in which they interact.

Social Field

We have said that when one contextual level or sphere is embedded within another, the embedding level inherits certain properties from the embedded one, that it transforms it, and that it serves as the operative horizon against which the embedded level is grasped. In these terms, we can say that any demonstrative field is embedded in one or more social fields. The term 'social field' as used here is adapted from practice sociology and designates a bounded space of positions and position takings, through which values circulate, in which agents have historical trajectories or careers, and in which they engage on various footings (e.g., competitive, collaborative, collusive, strategic). Thus defined, a social field is neither radial nor discourse-based, although discourse circulates in most fields, but there are interactive settings embedded in any social field. What is different about a social field is its scope (nonlocal), the way it is organized (nonradial), the character of the boundary (credentials and limited access as opposed to the gradual boundaries and relatively open access to demonstrative fields), and the values that circulate in it (e.g., economic, symbolic capital and power as opposed to meaning production through indexicality, reference, and description). Moreover, whereas participants in discourse production are traditionally conceived as individuals (hence interaction means intersubjective engagement), the agent positions in a social field can be occupied by collectivities (e.g., professional organizations, 'communities,' classes, departmental staff), whose interactions are typically mediated by writing, electronic media, and other instruments. Under this definition, a hospital, university, profession, academic discipline, a courtroom, a supermarket, an airport, a religious congregation, and a neighborhood are all social fields. This does not mean they are all equivalent or that any one of them may not itself be embedded. It does mean that these and other social formations provide critical embedding contexts that shape radial, interactively centered demonstrative fields.

The social field places constraints on who has access to the participant roles of Speaker (Spr), Addressee (Adr), overhearers (ratified and unratified), the sanction to participate in a capacity, the requirement to manage face in specific ways (Goffman, 1967), and so on (see Face). In the demonstrative field as such, there are no constraints on who can play what role in acts of reference, directing of joint attention, or semiotically proper indexicality. It suffices that the participants master the language and be in the natural attitude. But this is not true in a social field, in which access to different positions is constrained,

the authority to speak in certain terms and to specific others is restricted, and the capacity to monitor another is a selective right or even a responsibility, not a mere existential condition.

In the kinds of organizational fields listed above, there are also many virtual counterpart relations, such as the correspondence between the patient and the X-ray image, the cash register number and the cashier, the evidence and the now-past actions that produced it, the paper and its author. These correspondences create networks of counterpart relations between objects in the immediate demonstrative field and ones that are absent (in other places or other times). Careful study of deictic practice shows that such counterpart relations play a formative role in how participants resolve indexical reference. The implication is that in order to understand simple indexical practices, we are forced to look beyond the immediate field of copresence, just as participants must do in order to get the point of utterances. In order to explain the actual functioning of the *Zeigfeld*, then, we are obliged to look beyond it to the social field. These are all embedding effects and the social field is unavoidable in any description of indexical practice.

Settings and demonstrative fields are designed so as to project them into further embeddings. Any relevance system ties its thematic focus into a history of other engagements with the object, a horizon of other related objects, a set of judgments regarding what is interpretationally relevant and what can be ignored. Hence, the setting is already rooted in a world beyond itself. Once we introduce semiosis, we have aboutness relations, and not all objects stood for are copresent in the situation. Furthermore, the symbolic categories themselves tie the sign and its object into other signs and objects *in absentia*, as Saussure put it.

Two rather different transformations take place in the embedding of a demonstrative field in a social one. The social field is made actual, we might say, localized, by its articulation via relevance, symbolization, and indexical invocation (all the better if it is explicitly formulated, although this is not necessary, as we have seen). This is a genuine transformation because the social field does not owe its structure or existence to the kind of radial, intentional structures into which it is recruited by signs (the world is not organized in the same way as the language that refers to it). The second mode of embedding is occupancy: the actor occupies a participant role, which occupies an agent position (Dr. Jones speaks as an expert performing a procedure). The copresent setting occupies a socially defined site (the relevance system and actions in progress are procedures in a medical

clinic). The referent-object occupies a socially defined position (the needed instrument in an ongoing procedure). Hence, the embedding social field provides a space of positions (including referent positions) and those positions are occupied or taken up by the various elements inherited from the embedded demonstrative field.

Embedding is a process in time, and a proper study of context at the level of social fields must attend to the temporal order of occupancies, including the careers of persons, objects, places, and actions in the time course of the organization. The social field has a history that transcends any particular occupancy. The clinic outlasts Dr. Jones, just as it outdistances the single office he occupies on such and such an occasion. Utterance-to-utterance temporality at the level of the demonstrative field is embedded, and hence transformed, in the broader history of the field.

Looking across the communicative practices embedded in one or more social fields, it becomes possible to ask which elements remain relatively invariant across embeddings, and which ones are subject to transformation. The distinctions between Spr, Adr, Object, the semiotic means of thematization, the omni-relevance of perception and the procedural organization of turn-taking (Schegloff, 1987) may remain constant, for instance, even if differentially realized and constrained in different fields. Such invariance contributes to the partial autonomy of the demonstrative field across embeddings. Inversely, certain features of social fields may function as relatively constant constraints or resources for any demonstrative field that emerges within their scope of embedding. To that degree, these factors contribute to what Bourdieu (1993) called the “heteronomy” of the embedded fields. Autonomous features of any field derive from the field’s own organization, whereas heteronomous (nonautonomous) features derive from its embedding in some other field. Thus, we can ask of any discourse context: in what measure and in which features is it autonomous? It is standard in the literature on language to describe speech contexts as if they were highly autonomous, such as Bühler’s generalized *Zeigfeld* or the hackneyed Speaker–Hearer dyad of linguistics. But this nomothetic bias toward autonomous schemas hides heteronomous effects that are systematic and consequential for a theory of context.

The participants in any process of discourse production are clearly a key part of the context, whether they engage as individuals or groups and whether we treat context in local or nonlocal terms. In the discussion so far, there is an implicit series of embeddings of participants, from the individual subject to inter-subjective copresence (situation), to coengagement

(setting) to participant roles (demonstrative field) to agent positions (social fields). In a series of influential studies, Goffman (1963, 1981) brought attention to the differential kinds and degrees of involvement that parties to discourse sustain in social practice. He distinguished, for example, unfocused from focused interaction, the former pertaining to mere situations and the latter to settings in which the participants share a common attention focus and orientation (which he dubbed “encounters”). Given a focused interaction, the question arises as to the degree of intensity of involvement and the distribution of involvement among participants (over time). This in turn led Goffman to distinguish among contexts according to how they regulate involvement, the embodiment of that regulation in space and physical conduct, the penalties for inappropriate involvement (invasion, exclusion, drifting away, excess intensity), and the overall “tightness or looseness” of contexts (Goffman, 1963: 198–210). Although this entire discussion is rooted in the phenomenological sense of subjective engagement, it can be analogically projected to the level of social field and the agent positions they entail. Here, involvement has to do with modes of occupancy of positions, how tight or loose a field or a position is, the degree to which occupying one position precludes or requires engagement with other positions, the vectors of access or exclusion provided by given positions, the means of displaying or concealing involvement, the varieties of collusion or competition that are differentially built into sectors of the field. In short, the embedding of discourse production in social fields defines a space of involvement among agents.

Whereas most of Western language theory has posited a speaking subject endowed with free will and uncurtailed intentionality, social theory has long debated the extent to which social actors and actions are determined by social forces external to them. This has given rise to a host of concepts significant in the study of context, including structuration, subjection, ideological state apparatuses, and habitus (Bourdieu, 1977). Notwithstanding significant differences among them, these ideas have in common the basic observation that social actors, from subjects to collectivities, are not given by nature but are, in critical ways, produced by society. Such ideas turn individualism on its head by asserting that not only is the ‘natural subject’ not the starting point from which society is produced, but the subject is itself, already, a social production. The importance of this line of thought for a study of context lies in the challenge it poses to any theory of meaning production that starts with individual intentions and phenomenal situations in order to then derive context by addition of external

factors (a view pervasive in language sciences). From the vantage point of social fields, the corresponding question would be to what extent engagement in a field shapes the participants not only in their agent-based external engagements, as it were, but more pervasively in their habits, dispositions, and intentions. In other words, there is a tipping point at which context ceases to be conceivable as the layering of structure upon intersubjective copresence and becomes the very **production** of subjects and the condition of possibility for intersubjectivity. Our definition of embedding as entailment, partial inheritance, transformation, and the necessary horizon for any contextual factor foreshadowed this shift.

In practice theory, the idea of a field is intimately related to the notion of habitus. The former defines the space of positions and position takings and the latter defines the social conformation of agents who engage in the space. There are four principal sources of the idea of habitus, which will help clarify its meaning. First, the Aristotelian idea of hexis, which joins individual desire or disposition with the evaluative judgment of what is good. If these two are aligned, we might say, the person is disposed to act in ways that are good. A linguistic analog might be interactive hexis, as evidenced in the spontaneous desire that good speakers have to be cooperative interlocutors or to say the right thing at the right time. Second, the phenomenological idea of habit and habituation as developed in the writings of Husserl, Merleau-Ponty, and Schutz. The idea is that in the course of ordinary experience we habitually engage in certain ways, we tend to routinize and typify. Under various guises, the idea that Sprs use language in habituated, routine ways has been a staple in the study of language for the last half century or more (cf. phenomenologists, Sapir, Whorf, Garfinkel, conversation analysis, ethnography of speaking). The third source of habitus is the idea, made prominent by Mauss (1973), that human beings conduct themselves physically in culturally patterned, habituated ways. Mauss was concerned with such phenomena as walking gait, posture, ways of carrying oneself, the management of body space in social settings (like waiting in line), socially standardized gestures (whether actually conventional, like the thumbs up gesture, or not), standard ways of holding objects, such as tools, of covering or revealing parts of the body. Mauss' insight was that these myriad aspects of how social actors inhabit and act through their bodies are socially patterned. Notice that, while some of this is explicitly taught to children and sanctioned, such as proper modesty or table manners, other aspects are merely instilled by habit and the tendency of human groups to routinize. The linguistic analogue to this

would be utterance production as a corporeal activity, subject to habitual voice modulation, pacing, posture, degrees of involvement, and their embodiments.

The fourth source is the scholastic philosophical idea of habitus, meaning mental habits that regulate acts. This idea most decisively entered into practice theory through the writings of the art historian Erwin Panofsky, whose work Bourdieu translated and considered fundamental to his theory of practice. For our purposes, the most salient lines of argument in Panofsky (1976) were these:

1. In a given historical conjuncture, there exist underlying mental habits that guide people's cultural production in different spheres (such as philosophy and architecture in 12th–13th century Paris).
2. These habits are instilled through education.
3. They come to guide both how actors act and how they evaluate acts.
4. They are realized in works.

Thus stated, the habitus is a *modus operandi*, flexible enough to be realized in different works, every one of which is unique, and in different spheres of work, which may differ widely. From a language perspective, the habitus would involve discourse genres (Hanks, 1987; Briggs and Bauman, 1992), routine ways of speaking and interpreting speech, and the habits of mind implicit in standard ways of representing the world in language.

As used in practice theory, the term habitus bundles these four sources into a single idea. It therefore claims that there is a basic unity between the disposition to speak in certain ways, the evaluation of speech, the bodily habits enacted in speech production, and the mental habits instilled in speakers as social beings. What unifies this set of features is not logical necessity, but historical necessity. Habitus is individual, since it forms individual persons, and collective, since it is a social formation. It joins the body with the mind rather than asserting the division and priority of either one over the other, as is more typical in language studies long dominated by mentalism. Finally, it is an alternative vision of the speaking subject, openly contradictory of the traditional idea that speakers are freely intending persons whose inner mental states (propositional attitudes, intentions) are the source of discursive meaning.

The relation between habitus and field is subtle and far-reaching. On the one hand, the habitus is usually associated, in writings on practice, with the social provenance of the individual in terms of class, gender, ethnicity, and other macro-sociological divisions. It is inculcated in childhood, primarily in the domestic field and through more or less formal education. It is reinforced and reproduced in ordinary social life in

these spheres and also in labor practices, which exert particular influences (including agriculture among farmers, research, writing and teaching for an academic, painting for a painter and so on, driving for a cabby, etc.). Any form of ritual practice has a potentially strong impact on habitus, by dint of engaging the dispositions, evaluations, body and mental orientations of practitioners through the repeated doing of practice. The important point is that there is a dynamic (if not dialectical) relation between contextual embedding and the formation of the actors who engage contexts. Language and discourse are among the central modalities through which the dynamic is articulated.

How do participants enact their positions in the field so as to achieve their communicative goals? How do they decide on goals and plausible ways of achieving them? Which strategies and moves are permissible or effective in a given field, and which are ineffective or impermissible? The idea that speakers are strategic is widely accepted in discourse studies. Gumperz's (1992) work on discourse strategies effectively shows that with contextualization cues, speakers strategically position themselves and frame the interpretation of their utterances for their own ends. Grice's (1989) theory of implicature rests on a model of the speaker as one who pursues communicative ends through "implicature," by deriving and conveying complex conversational meanings with underspecified statements, formulated so as to be expanded by inference. The speaker in an inferential language game must be strategic if only to properly attain such subtle and understated affects. Similarly, conversation analysis envisions the speaker in interaction as an active maker of context, one who masters the procedural system of turn taking, the conditional relevances of conversational moves, knows how to hold the floor, call for a repair, invite or block certain inferences. In general, the exemplary speaker talks on purpose and pursues practical ends by more or less effective means, in more or less locally defined contexts. To call this 'strategy' invites the assumption that it is elaborately thought out, which is sometimes true, but not always. Whether full-blown strategies or mundane purposive gambits, discourse strategies have a double relation to the field: they may be called forth by context or they may produce it anew. If context bears an unavoidable relation to the habitus of those who occupy it, it is also subject to the purposive projects and strategies they pursue.

Contextualization Processes

In the course of spelling out a minimal architecture for discourse context based on embedding and emergence, we have made reference to a number of

processes. As we have emphasized, all of the units involved emerge in time, albeit at different levels, and embedding itself is a dynamic process. At this point I want to draw together and offer a preliminary summary of the processes through which context occurs. The first class of processes involves intentionality, in both senses of representation and purpose. Thus, when a speaker pays attention, thematizes, formulates, or invokes context, he or she converts it into a semiotic object in a standing-for relation. Similarly, when the speaker uses grammatical, intonational, or gestural means to cue his or her current footing and to contextualize the current utterance, semiotic relations are produced between the expressive stream and the context of its expression. In deictic usage, speakers construe context, signaling both the referent and the perspective under which it is individuated. Austinian performatives (Austin, 1962) rest partly on the intentionality that links the propositional content to the conventional act type, the locutionary act to the illocutionary (see **Speech Acts and Grammar**). The kinds of creative indexicality revealed by Friedrich (1979), Silverstein (1976), and others all involve the consequential use of signs to invoke contexts and thereby bring them about. Through intentionality, signs and expressions project their objects and thereby alter context. Inferential processes (interpretation, extrapolation, implicature, contextual enrichment) also operate on expression forms in the light of contexts, with special importance given to relevance structures. All of these processes rely critically on the capacity of participants to produce and evaluate signs of context, and to do so on purpose. Strategy and improvisation are ways of exercising this capacity.

But we have also mentioned processes that are not subject to the intentionality of participants, at least not necessarily. This is a different class of phenomena. From situations to settings, demonstrative fields, and embedding social fields, we have said that objects, persons, and groups occupy positions in context. This occupancy is not a standing-for relation, and it may or may not be subject to the purposes of the actor. If a police officer calls to me on the street, I am interpolated into a position, whether or not I wish and whether or not I produce a sign of my position. When I go to the airport and pass through security, I occupy the position of a ticketed passenger to be inspected whether I wish to or not, just as I become a customer when I sit in a restaurant. Occupancy can be described as 'taking up a position' but it also designates 'finding oneself in' and 'being put in' a position. When persons or objects are referred to in discourse, they are thereby thrust into positions and the social relations that define them. The key point is that the positions and the process of occupying them

are social facts at least partly independent of the intentional states of the participants.

Another contextual process whose source is beyond the scope of intentional action is what might be called over-determination. The social field in which an interaction is embedded does not determine what participants do, or how context emerges. But it does make certain contextual configurations and actions more likely and predictable. It reinforces and calls for them the way the operating room calls for a certain engagement from the medical experts working in it, or the courtroom calls for specific forms of engagement on the part of its occupants. The acquired habitus of a practitioner of any profession is reinforced constantly by the settings, rights, responsibilities, and routine practices that make up the field. Along with the training that inculcates ways of seeing appropriate to the profession, these aspects of the field reproduce, sanction, and guide contexts and ways of occupying them. We will say that embedding over-determines context when habitus, field, built space, and sanctioned practice align to impose or induce specific features of context. Organizations, religious and missionary settings provide clear examples of this, but the effect is much more widespread.

Social fields also authorize and legitimate certain contexts and modes of engagement, but not others. A cashier has the authority to tell you how much you owe for a product, just as a doctor has the authority to classify your body states and a teacher is authorized to evaluate your work. This authority is enacted in intentional processes, but its source is the field, not the intentional states of individuals. We describe it as a process and not an attribute in order to foreground the dynamic whereby authority is conferred on certain contexts and agents in them. Legitimacy could also be conceived as an attribute of contexts and actions, but is more productively viewed as the process whereby they are aligned to the values of the field. In the same family of phenomena, Ide (2001) distinguished between volitional aspects of discourse production and nonvolitional 'discernments' of context. The latter designated the process whereby participants construe and align themselves to the field-based requirements of context, such as when they use Japanese honorifics unreflectively and automatically, out of a habitus-like sense of what is called for. Any of these processes may involve intentionality, but they illustrate the capacity of fields to exert a structuring influence apart from intentionality.

Conclusion

Discourse context cannot be formulated as a set of correlations between global, macrolevel social

features and local, microlevel ones: correlation is far too crude for the kinds of articulation in play. It cannot be described as the reproduction of macrolevel types at the token level: speech is productive and inherently situated. It cannot be derived by sheer seat-of-the-pants creative expression guided by purely local intentions and relevance systems: we do not simply fabricate the contexts of our discourse whole cloth. In short, the social horizon of discourse production requires that we use a different vocabulary. Two key terms in this new lexicon are emergence and embedding, and together they define a space of contextualization more productive and realistic than any of the familiar divisions of scale. Embedding describes the relation that holds between situations, settings, demonstrative fields, social fields, and habitus. These have the status of analytically isolable levels in the overall architecture of context. For any level X embedded in Y, Y entails X, Y inherits features from X and adds others, Y transforms X on several distinguishable dimensions (temporality, participation, weighting of factors), and Y serves as the presumptive horizon of X, held ready for thematization and relevance relations. Embedding is more basic than correlation, instantiation, or reproduction, because it is the objective condition under which these occur.

Some features of context follow from the distinct logic of the level at which they arise, whereas others are imposed by embedding. The sheer copresence of the situation, the relevance of the setting, the semiosis of the demonstrative field, the constraints and resources of the social field, the bodily dispositions of the habitus – any of these may be relatively free from the structuring effects of the fields in which they are embedded. To the extent that this is so, the contextual level to which they belong is relatively autonomous. By contrast, to the extent that some process at a given level is determined by its embedding in another field, it is nonautonomous. The functions that make up the demonstrative field, for instance, are relatively autonomous, whereas those that count as mutual monitoring and relevance are not, because they depend on the field in which they are embedded. Similarly, the resolution of ordinary indexical reference is nonautonomous.

Emergence is a pervasive feature of context, which is dynamic along several trajectories at several levels. What we might call context time precipitates from the interaction between distinct temporalities at the levels of situation (body time), setting (act time), demonstrative field (time formulated and invoked with signs, themselves produced in time), social field time (careers, historical revaluation of positions, objects, and what is at stake), and

habitus time (embodied mental and physical habits, routinizations, alignments of disposition with evaluation). Just as time and participation are defined by copresence at the level of the situation, by cognitive engagement at the level of the setting and agent positions at the level of the field, so too other aspects of context emerge in different temporal streams. It is only in practice, especially communicative practice, that they are synchronized to one another. Context occurs when multiple temporal relations are articulated to one another in the emerging actuality of practice.

Behind the standard divisions of scale in context lies a more basic distinction between context-building processes that presuppose individual intentionality, and those that do not. The latter derive directly from the field in which communicative practice is embedded. Intentionality encompasses purposes (as in I intend [to] X) and aboutness relations (I am talking about X). For any student of language, it is doubtful whether the dispositions, mental habits, and embodiments of the habitus can replace intention as a motor for action, as Bourdieu suggested. It is difficult to imagine a theory of language or discourse context that exempted itself from aboutness relations or purposive action. Yet the habitus and the current state of the field cooperate on the intentional states of those that occupy them. They provide a ready-made universe of objects and agents, frames of reference, spaces and evaluative stances – the very stuff of context.

Conversation Analysis

Introduction

What kinds of social organizations are used as resources when people communicate through talk in interaction? It is this question that conversation analysis attempts to answer. Conversation analysis (CA) studies the methods participants orient to when they organize social action through talk. It investigates rules and practices from an interactional perspective and studies them by examining recordings of real-life interactions.

Although conversation analytic research may be subsumed in typically linguistic disciplines such as pragmatics, discourse analysis, or (interactional) sociolinguistics, it started in American sociology. In particular, the sociologists Erving Goffman (see **Goffman, Erving**) and Harold Garfinkel prepared the ground in which CA arose – Goffman with his study of cultural rules and rituals in face-to-face interaction (Drew and Wootton, 1988), and Garfinkel with his investigations into the situated and normative character of shared understanding in everyday courses of action (Heritage, 1984). Enabled by the spread of recording techniques that opened new ways of inspecting interactional data, Harvey Sacks (†1975) and Emanuel Schegloff established a novel paradigm for researching the organization of human action in and through talk in interaction (Schegloff, 1968; Schegloff and Sacks, 1973; Sacks, 1992) (see **Telephone Talk; Sacks, Harvey**). Although the foundational work in CA focuses on talk in conversations, the framework has gradually been extended to research of other types of talk such as medical and clinical interaction, lessons, or news interviews. This is why the more general characterization 'talk in interaction' nowadays is often preferred over 'conversation.'

Studying Transcriptions of Recorded Talk

In conversation analysis, the investigation begins with making an audio and/or video recording of naturally occurring talk. These recordings are carefully transcribed according to specific conventions first developed by Gail Jefferson (see Jefferson, 2004). The *CA transcription notation* is designed for rendering details that contribute to the organization and intelligibility of talk. It helps to retain features of prosody and turn positioning in the transcription. Together with the original recording, the transcription enables researchers to examine the forms of language use that were available to the participants in the recorded interaction itself.

A CA transcription is still readable without considerable expert knowledge. The transcript does not represent speech production at the level of its mechanical reproducibility (the *etic* approach that is typical of phonetics). Rather, the transcription provides an empirically reliable approximation of the interpretative assemblies that participants in talk are working with (the *emic* approach). A transcription is the combined result of carefully listening to how and where utterances are produced and the interpretative work of the transcriber as a competent member of the culture under investigation.

Extract (1) exemplifies this way of transcribing talk. It documents a short episode – just 7 seconds – from a Dutch telephone conversation (the original text is followed by an English translation in italics):

Extract (1). Telephone call between brothers. Background information: Jan is calling his brother Ton from their Rhine barge. Their parents sail a barge as well. Ton is in the office of the shipping exchange. Caller Jan is inquiring whether their mother is also at the shipping exchange.

54 Jan: mamah, (0.2) is die d'r ook?
mama (.) is she there too?

55 0.4
 56 Ton: HĒ↑:h?
huh?
 57 (.)
 58 Jan: mama:h
mama
 59 0.6
 60 Ton: waa:r
where
 61 0.3
 62 Jan: is die daa:r?
is she there?
 63 0.3
 64 Ton: ↑hie↑:r?
here?
 65 (.)
 66 Jan: j[ah
yes
 67 Ton: [nEEj!
nO!
 68 (.)
 69 Jan: °oh:°
 70 0.6

In order to be able to read a transcription like this one, the reader has to know the conventions. Notice first that each speaker contribution – or *turn* – has a separate line. This indicates the turn's chronological position relative to its predecessor and its successor. Other notation conventions include:

- 0.6 The length of silences between and within turns is measured in tenths of seconds.
- (.) A dot between brackets (.) indicates a short silence of less than 0.2 seconds.
- [In the case of simultaneous talk, the onset of the overlapping turn is located by a *left square bracket* in the overlapped turn.
- . , ? A *period* indicates a falling final pitch contour, a *comma* a slightly rising pitch contour, and a *question mark* a strongly rising one.
- ↓ ↑ Vertical arrows provide information about local pitch movements within syllables or at the level of a single syllable. A *downward arrow* signals a falling tone movement, an *upward arrow* a rising one.
- word *Underlining* signals salient stress.
- wor:d A *colon* renders a noticeable sound stretch.
- sto- The *hyphen* is used as a cut-off marker.
- >faster< This utterance part is produced with higher pace than the talk surrounding it.
- <slower> The pace is relatively slower.

- LOud *Capitals* indicate relative loudness.
- °soft° The *degree sign* signals that an utterance part is produced more softly than the surrounding talk.
- ·h Hearable inbreath.
- hh Hearable aspiration.
- (guess) The transcriber is uncertain about the utterance part between parentheses.

Even the transcription of a brief episode such as the one documented in extract (1) already displays very basic features of talk in interaction. Note, for a start, how short turns may be. If the reader was expecting utterances in turns at talk to consist of complete, well-structured sentences, he will be surprised to find out how little the participants need to achieve meaningful verbal interaction. How do they do this? This question will be answered by looking at two levels of the organization of talk that are central in conversation analytic research: turn taking and sequence organization. The interaction in extract (1) shows that the participants know where and how to change the roles of speaker and listener. How they manage this is the subject of the section about the organization of turn taking. Second, the talk in this fragment is an interactionally coherent exchange of communicative actions. The episode starts with a question and it ends with the answer to that question (see lines 54 and 67, respectively). How are we able to recognize this kind of interactional order in a series of utterances? How is it achieved? This question is answered at the level of sequence organization, that is, the way in which participants coordinate actions in series of turns in order to effectuate interactional projects.

Turn Design and the Organization of Turn Taking

A remarkable feature of the interaction in extract (1) is that speaker change is coordinated smoothly. Both interruptions (or other kinds of simultaneous talk) and gaps are relatively rare. In a seminal paper first published in 1974, Sacks, Schegloff and Jefferson formulate these observations in more technical, organizational terms; the participants display an orientation to minimization of overlap, while at the same time, they also orient to minimization of gap. Sacks and his colleagues account for this fine organizational balance by a description of the systematics that conversationalists orient to when they coordinate the organization of turn taking.

The basic organizational problem that participants have to solve each turn anew is to determine when the speaker will complete the current turn. The recipient

is not only figuring out what the turn is about and what the speaker is doing with it, he also has to be alert for the moment it might become his turn to speak. Recipients anticipate such organizationally relevant moments by building expectations as to what the utterance underway is going to look like. Turns are produced linearly in real time, but in the course of a turn's production, a recipient can make an informed guess about the structure of the whole unit by inspecting – in its environment of use – the part that is already there. The turn so far provides cues as to how the unit underway is constructed and when it will possibly be complete.

The building stones of turns are turn constructional units (TCUs). Each turn is built with at least one *turn constructional unit*. The design of a TCU may vary. A TCU can be built as a one-word unit, such as the turns with no more than the words *here*, *yes*, or *no* in extract (1). Other TCUs have a syntactically more elaborate design, such as the interrogative clause '*is she there too*.' Depending on the unit type the speaker is recognizably using for the construction of a TCU, the recipient will make different predictions as to when the ongoing turn may be complete.

The more complex the unit type is, the more faceted the projection of completeness. Compare the extract below. Angela begins a TCU with a particular type of subordinate clause (*(but) if you get them back*, line 321). This makes the unit underway analyzable as the first part of a compound TCU with an [*if ... , then ...*] structure. The turn will not be complete until the speaker has finished the *then*-part that is projected by the *if*-part:

Extract (2). Telephone call between two 17-year old Californian girls. Angela has just complained that Corey's friend has not returned three of her CDs.

321. Angela: → ·hhh (but) if you could get them
 322. back, (.) that be great.
 323. 0.2
 324. Corey: °'kay.°

Note that the recipient does not begin to speak when the speaker has finished the part with the *if*-clause. Even the short silence after it is not used as an opportunity for speakership transference. The recipient observably orients to the preceding clause as a preliminary component of a compound TCU with a two-part structure. It foreshows a continuation with a structurally specifiable type of second part as its final component. Only after the subsequent main clause implementing this latter part has reached completion, does the recipient take over (cf. Lerner, 1991, 1996).

Recipients may locate possible completeness on the basis of the interplay of syntactic and prosodic information. Whereas the TCU's construction type 'nominates' a place in an ongoing TCU as a syntactically plausible point of completeness, prosody can 'second' the nomination (Schegloff, 1998). For example, a speaker can stretch or reduce the vocalization of the intended last syllable of the turn, or mark it with a noticeable tone movement such as the falling pitch movement in the last word of Angela's turn in extract (2). **Figure 1** makes the intonation contour of this TCU graphically visible with the help of *Praat*, a program for the phonetic analysis of speech.

Figure 1 Prosodic analysis of the TCU in lines 321–322 of extract (2).

The lower half of the graph shows the fundamental frequency – an acoustic correlate of pitch – of Angela's TCU in Hertz. Note that the last two words of the TCU move toward a final pitch level that is noticeably lower than the base level of the preliminary component.

Construction type and prosody are not the only dimensions within which participants negotiate turn rights, however. The issue of whether an utterance is possibly complete strongly depends on pragmatic factors, most notably on how the ongoing turn is related to its immediate interactional context (*see Context, Communicative*). Single words such as *mama*, *where?*, *here?*, *yes*, or *no*, for example, can only function as meaningful independent interactional moves when uttered in a context that lends them this type of intelligibility.

Each utterance provides an ensemble of various types of cues that together project a *possible completion point* of an ongoing TCU. The first possible completion point of a TCU is the place where turn taking becomes an interactionally relevant issue. The participants of talk in interaction negotiate speaker transition around such *transition relevance places*. Conversationalists use specific techniques to allocate next turn. If current speaker selects another participant as next speaker before her turn has arrived at its first possible completion point (other selection), the selected party has both the right and the obligation to begin the next turn at this point. If no other speaker is selected, another participant may self-select as next speaker. If none of these options is used, current speaker may continue. The system then applies again as soon as current speaker arrives at the next possible completion point (Sacks *et al.*, 1974).

A TCU can function as an interactional move in its own right, and because of this, it may fill a turn slot on its own. On the other hand, turns may consist of more than one TCU (multi-unit turns). However, unless special provisions are made to maintain speaking rights over a longer stretch of talk – as is the case with, e.g., story telling (cf. Sacks, 1974) – each next possible completion point of a subsequent TCU is treated as a place where speaker transition is an organizationally relevant, negotiable issue.

Thus, the organization of turn taking is accounted for by describing it as a set of constructional practices that enable the co-participants to determine the place at which speaker transition becomes relevant and to then deal with that issue according to a structured set of interactional options. This way of modeling the organization of talk is characteristic for the CA approach. The methods that members orient to are described as formally and as generally as is necessary to account for the fact that people succeed

in managing turn taking in an orderly way, innumerable times a day, in all kind of situations. At the same time, the description has to explain how participants are able to shape and recognize each time anew the particular context in which the rules for allocating next turn apply. CA thus studies the organization of talk as situated, socially organized sets of practices. It describes the methods members use for organizing talk as interactional structures that both shape the context in which they operate and enable its orderly, interactionally coordinated progression.

The general model sketched in the initial paper about turn taking has been developed further and refined in work on systematic practices of overlap positioning and overlap resolution (Jefferson, 1986; Schegloff, 2000a), collaborative turn construction through anticipatory completion of compound turns (Lerner, 1991, 1996), and the role of gaze, gesture, and body positioning (Goodwin, 1981) (*see Gestures, Pragmatic Aspects*).

The general characterization of the systematics of turn taking has appeared to be very robust across languages. Depending on the structural features of specific languages, however, the linguistic practices deployed to project possible completion points of TCUs may vary. The structure of English, for example, allows for early projectability of the design of TCUs. Its strict Subject-Verb-Object (SVO) word order in full clauses, for example, enforces early positioning of predicates. Function markers such as question words, imperatives, conjunctions, or quote attributions occur in sentence-initial position, just as the inversion of subject and auxiliary in yes/no interrogatives enables early recognizability. A language such as Japanese, on the other hand, is said to have an SOV- or OSV-type of word order, an agglutinative morphology, and a preference for postpositioning over prepositioning of markers of syntactic, semantic, and pragmatic functions. These properties result in a predicate-final design of clauses in TCUs. Consequently, the construction of TCUs may display a delayed projectability of possible completeness. On the other hand, Japanese has the option of explicit markers of possible completeness such as final verb suffixes or final particles (cf. Tanaka, 1999). The differences in language structure lead to partially different sets of grammatical practices that are deployed for the interactional organization of turn taking. The general principles of turn construction and completion projection are nonetheless the same.

Sequence Organization

We now turn to the question of how an exchange like the one in extract (1) is easily understood as

a coherent episode. It is not just the linear temporal order of turns that accounts for our understanding. The series of turns has a structure. Some turns belong more together than others. The ways conversationalists link turns to other turns as coherent series of interrelated communicative actions is called sequence organization. A *sequence* is an ordered series of turns through which participants accomplish and coordinate an interactional activity.

A question followed by an answer is an example of a sequence. Other examples are a request and the decision that is made about it, an informative and its receipt, and a criticism and the reply to it. All these different types of two-part sequences are instances of a very tight type of sequence organization: the *adjacency pair* (cf. Schegloff, 1968; Schegloff and Sacks, 1973). When a recipient of a turn at talk hears the speaker's utterance as the first part of a particular type of adjacency pair, the appropriate thing to do next is to deliver an utterance that may count as the second part of the same pair. For example, the appropriate reaction to a question is to answer it. The question is treated as the first pair part of a question/answer pair; the answer is its second part. Requests, invitations, offers, proposals, informatives, complaints, or accusations establish similar expectations with respect to a continuation with a fitting type of second pair part in the next turn (see *Speech Acts*).

Extract (3) documents several instances of question/answer pairs. The first one starts in line 33. The son asks his mother a question, and at the first possible completion point of his turn, the mother takes over to answer it.

Extract (3). Telephone call between a mother and her son. Background information: The mother has called her son from the family's Rhine barge. The son is in a boarding school for bargee children.

- 33 son: nou[: >waar zittet jullie< nouw.
well where are you plural now.
0.2
- 34 mother: i:: >Amsterdam.<
i::(n) Amsterdam.
35 0.3
- 36 son: waar moe(we) almal heen.
where all do (we) have to go to.
0.3
- 37 mother: è†:h?
huh?
(.)
- 38 son: waar moewe heen
where do we have to go to
- 39 mother: naar Luik.
to Liège.
0.2

- 40 son: naar Lui:k?
to Liège?
- 41 mother: jah.
yes.

When the mother treats the utterance in line 33 as the first part of a particular type of adjacency pair, she is dealing with it as a specific type of social organization. She does not just hear an interrogative sentence that, under felicitous conditions, may count as a separate speech act; she hears it as an utterance that proposes her engagement in an interactional course of action. When an utterance is analyzable as the first pair part of a particular type of adjacency pair, it locally establishes a normative expectation toward what its recipient should do in next turn. The first part makes the delivery of a fitting second part *conditionally relevant*. That is, its recipient is expected to deliver the second part in his next turn. If it is absent, this is noticeable and accountable (cf. Schegloff, 1968; Heritage, 1984). The obligation to deliver the second pair part as soon as possible in next turn may be suspended, however. Compare, for instance, the mother's response to her son's next question in extract (3) ('where all do (we) have to go to'). 'Huh?' is not an answer. Instead of answering the question, the mother initiates *repair* (cf. Schegloff *et al.*, 1977; Schegloff, 1992, 2000b). She signals that she is having a problem with prior turn. The son's subsequent, slightly modified repetition of his question apparently solves the problem, because the mother is able to answer now ('to Liège'). Unlike the first question/answer sequence in this episode, the answer is not delivered in next turn. A short repair sequence is inserted between question and answer. Schematically, this can be rendered as shown in Figure 2.

An *insertion sequence* like the repair sequence in lines 37–38 locally suspends the interactional expectation to deliver the second pair part in the turn following the one with the first part. The intervening interaction shows that the participants nevertheless are still oriented to the relevance of the second pair part. The repair sequence is recognizably supportive of the felicitous development of the base sequence in which it is embedded. The delivery of the answer

Figure 2 Sequential structure of the interaction in lines 36–39 of extract (3).

is still pending. The urgency to answer is only temporarily postponed. Note that the questioner even renews the actuality of getting an answer by redoing his question in the repair itself, thereby creating another opportunity to hold on to the preference for next-positioning of first and second pair parts. And, by the way, note also that the inserted repair sequence is again structured by principles of adjacency pair organization!

Conditional relevance is also the key for understanding the structure of extract (1). We are able to understand the interaction in extract (1) as an orderly, methodically achieved sequential course of action on the basis of the adjacency pair structure. For the reader's convenience, the fragment is repeated below:

Extract (1). Telephone call between brothers.

- 54 Jan: *mamah*, (0.2) *is die d'r ook?*
mama (.) *is she there too?*
- 55 0.4
- 56 Ton: *HE↑:h?*
huh?
- 57 (.)
- 58 Jan: *mama:h*
mama
- 59 0.6
- 60 Ton: *waa:r*
where
- 61 0.3
- 62 Jan: *is die daa:r?*
is she there?
- 63 0.3
- 64 Ton: *↑hie↑:r?*
here?
- 65 (.)
- 66 Jan: *j[ah*
yes
- 67 Ton: *[nEEj!*
nO!
- 68 (.)
- 69 Jan: *°oh:°*
- 70 0.6

The question in line 54 urges its recipient to deliver an answer as soon as possible. Its delivery is, nonetheless, suspended three times by the initiation of repair from the part of the intended answerer (lines 56, 60, and 64). Each next repair initiation builds upon the result of the former one, until the recipient of the question finally is able to answer it in line 67. The sequential organization of this episode can be schematized as shown in Figure 3.

The interaction in extract (1) is tied together by the way the utterance in the first turn is sequentially related to the one seven turns later. The question in line 54 makes an answer conditionally relevant, and

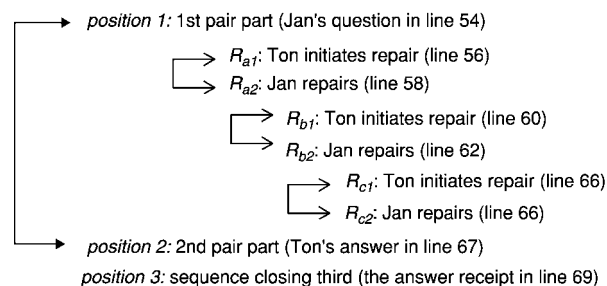

Figure 3 Sequential structure of the interaction in lines 54–69 of extract (1).

as long as this answer is not given, the participants work collaboratively toward an occasion in which it can be delivered. All intervening actions are recognizably designed as subsidiary to the task still pending. They should enable the recipient of the question to answer it, and as such, they account for the answer's postponement in each subsequent turn.

The interactions in extracts (1) and (3) clearly illustrate that the practices through which conversation-alists make sense of turns at talk are based upon *sequential reasoning*. A turn such as '*in Amsterdam*' in extract (3) can only be interpreted within the context of the question it is answering. The expression is not just a place formulation. As a place formulation, it is answering the question where the family's Rhine barge is at the time of asking. The structure of the TCU as a lone standing prepositional phrase even signals the kind of action it is designed to accomplish in its environment of use. The combination of the turn's position and the composition of the TCU together signal answerhood. It informs the recipient about how the turn should be related to its local sequential context. The identification of this relation is part and parcel of determining what a speaker is saying and doing. Interpretative reasoning goes by lines of sequential organization.

Utterances in turns at talk accomplish actions that are part of social activities which are sequentially organized and have sequential implications for the participants. In this section we have only looked at one type of sequence organization – the adjacency pair structure – and the way it can be expanded by sequence insertion. Central to this perspective is the insight that utterances do not just simply count as isolated 'actions.' Participants in talk in interaction orient to them as moves in contextually situated social arrangements. Participants in talk in interaction do not attribute meaning to utterances by simply applying rules that are independent from and external to the interaction. They make sense of utterances in turns at talk by situated, sequential reasoning.

Conversation Analytic Methodology

Conversation analytic methodology is based upon the already discussed assumption that the sense-making devices that participants in talk in interaction orient to can be understood as forms of situated, interactional reasoning (cf. Heritage, 1984; ten Have, 1999). This kind of contextual reasoning can only be investigated from *within* the interaction. The central requirement of CA methodology – convergence between the analyst's perspective and the perspective of the participants – attempts to achieve this. The analyst has to make plausible that his or her results are indeed a description of the methods that the participants themselves orient to.

The Data

In order to avoid problems with respect to the ecological validity of data, naturally occurring interactions are strongly preferred. They are recorded and transcribed according to the conventions discussed earlier. The transcriptions are used to generate initial ideas about how people communicate in talk in interaction. These ideas are worked out by looking at other instances of the same phenomenon. As a result, the description is gradually broadened and cyclically refined by falsifying or validating evidence. Additionally, transcripts allow the researcher to make her data available to the scientific community. The data are retrievable for the audience. Other students are enabled to redo and to check the analysis.

Analyzing Data

Conversation analytic methodology is strongly data driven. There are two kinds of studies. In a *single case analysis*, the researcher develops an analysis of the interaction in a single episode with respect to some interesting or relevant aspect. In a *collection study*, the analyst generalizes the results of a cumulative series of single case analyses with respect to a specific aspect. All cases are compared with respect to some feature by describing how, and the degrees to which they are the same, similar, or different.

Single case analyses serve purposes such as generating ideas that have to be grounded in a collection study, testing and applying the results of collection studies, or exploring the interplay of constellations of practices in episodes of talk in interaction. Collection studies have two phases (cf. Heritage, 1995). In the first phase, the analyst describes regularities with respect to some particular aspect of the data and develops a description of a candidate pattern by going from case to case in a corpus of transcripts. The description of phenomena is both formal and situated. A description is formal when it is formulated at a level of generality that allows for a characterization of the recognizability

of a device across contexts. A description is situated when the context is specified. We can discern distinct levels of description: the level of turn design – practices of turn construction or 'packaging' – and the description of the kind of social action that is implemented by practices of turn construction at a sequential level.

In a second phase, the analyst attempts to meet the requirement of convergence between the participants' and the analyst's perspective, and has to prove that the participants observably orient to the candidate pattern. A keystone procedure to do this is deviant case analysis (cf. Schegloff, 1968); the analyst examines cases where some departure from the described pattern can be observed. Examination of deviant cases either results in a modification of the theory developed so far, or it can be shown that a boundary case eventually provides some kind of second-order validation of the basic pattern. The latter is frequently the case with conversational repair. Conversationalists frequently undo departures from the patterns used. Such cases convey how and to what extent the participants are oriented to the principle that the analyst tries to establish as a pattern. Remember, for instance, how departures from the principle of conditional relevance in extracts (1) and (3) eventually confirmed a participant orientation to that very same device. The participants maintain the rule of having to provide a fitting second pair part by solving the troubles they encounter in trying to obey to the rule. Usually, phases 1 and 2 are repeated recursively. The ideal is to achieve an exhaustive description that accounts for all instances of the phenomenon in question in the corpus.

Quantification may play a role in determining the distribution of the observed pattern. Quantitative processing of the data, however, is subsidiary to qualitative exploration of the phenomenon in phase 1 and to qualitative validation of the candidate description in phase 2. Distributions that confirm a hypothesis primarily establish regularities. The researcher still has to provide qualitative evidence that the participants observably orient to such a pattern as a normative interactional rule. If the analyst is able to demonstrate that conversationalists orient themselves by the principle in question and to give a plausible account of how they do this, this accounts for the regularities.

The next section gives a short demonstration of a conversation analytic way of working. A single case will be discussed in order to explain how it confirms a general pattern. The case analysis describes an aspect of sequence organization that is called preference organization. In this case, the preference of agreeing over disagreeing assessments will be looked at. The analysis shows that the orderly packaging of

systematic sequential alternatives allows for inferences that are part of the interpretative procedures participants use to make sense of talk.

Preference Organization

The excerpt below is taken from a telephone conversation between spouses. The wife has called her husband late at night in his restaurant bar. The episode starts with the husband introducing a new topic. He tells how business is doing tonight. This report is concluded with a summary assessment: ‘*so u:h it’s much better tonight than expected*’ (lines 41–42). When his wife parsimoniously confirms this evaluation by only saying *yes*, the husband is not content with this response. It is challenged almost immediately (‘*so what?*’, line 46):

Extract (4). Telephone conversation between spouses. Background information: In the preceding episode, Ans has blamed her husband for failing to answering the phone earlier that evening.

 no you don’t have to,

The wife does the kind of metatalk we all know from our own quarrels. Acting as a competent lay linguist, she formulates explicitly what she meant with her response: ‘*if I say yes, (..) in other words, that’s fine (..).*’ In her version, the husband has misunderstood her completely. When reacting with *yes*, she was giving an agreeing, even approving response. The question is, however, whether the husband indeed did misunderstand her. Did he have any conversational evidence for an alternative interpretation when he threw doubt upon his wife’s response?

In order to be able to answer this question, we have to go back to the sequence that occasioned the dispute. The utterance ‘*so u:h it’s much better tonight than expected*’ (lines 41–42) is an assessment. It is an interactional property of *first assessments* that when its recipient is also knowledgeable about the evaluated object, a second assessment is expected from the part of that party. *Second assessments* have the property that they find their measure in the assessment they are responding to. Second assessments are never neutral; they either agree or disagree with the first one. Disagreeing assessments are more delicate actions than agreeing assessments. Participants in talk in interaction treat a disagreeing second assessment usually as a less preferred type of next action than its agreeing alternative. They are

nonequivalent alternatives. Agreement is preferred and unmarked; disagreement is dispreferred and marked. Preferred second pair parts are delivered without delay and formulated in a frank, concise mode. Dispreferred seconds, on the other hand, are frequently delayed, mitigated, hesitantly produced, hidden away, put or accounted for in a roundabout way (Pomerantz, 1984; Schegloff, 1995).

The ranking of sequential alternatives with respect to their relative degree of preference is called *preference organization*. The preference for agreement is just one type of preference organization. A related type of preference organization is the preference for project success. It accounts for the preference for second pair parts of adjacency pairs that bring about the result targeted in the interactional project that is initiated with a first pair part, e.g., getting an answer to a question, accepting an invitation, granting a request, affiliating with a complaint, etc. Participants' orientations to preference organization is a major source for *sequence expansion* of adjacency pairs (Schegloff, 1995). Participants may probe and try to preempt the likeliness of a dispreferred second pair part in a *presequence* (Schegloff, 1980). They may initiate repair on first pair parts in *insertion sequences* in order to provide an opportunity to adjust the preference structure of the preceding first pair part, or to at least delay the delivery of a dispreferred second pair part. And they may try to revise or to accommodate a preceding dispreferred second pair part in various types of *post-expansion* (Schegloff, 1995) – as in the kind of post-expansion that can be observed in extracts (4–5). The relational implications of types of interactional alignment and disalignment that are governed by preference organization are also investigated from the perspective how participants negotiate *epistemic rights* (Heritage and Raymond, 2005; Stivers, 2005). For example, a co-participant may claim or give evidence for primary epistemic authority by the way he responds to a first assessment, although the response itself has a kind of secondness because it is done in a sequentially second position.

The notion of preference does not refer to psychological dispositions. It is a description of interactionally observable orientations of participants. Preference organization provides the participants with a subtle and powerful apparatus for making interpretative inferences. In extract (4), the husband uses it as a resource when he challenges his wife's response. In a context in which an agreeing second assessment is preferred, his wife avoids taking a stance. When she reacts with 'yes,' she merely acknowledges her husband's statement 'so *u:h it's much better tonight than expected.*' She does not affiliate with her husband, but responds in an evasive

manner instead. Her husband's reaction attends to precisely this aspect of her response. He challenges a weakly agreeing response in a sequential environment in which another alternative is more preferred. So, despite his wife's subsequent (re-)formulation of the meaning of *yes* as simply agreeing, the man nevertheless has good reasons to hear her response as a sign of reservation or even foreboding disagreement. From a sequential perspective, the response is not just acknowledging prior speaker's assessment. Saying *yes* in this context is rather deployed as a device to avoid agreeing. As a contextually specifiable selection of another alternative than the preferred one, it legitimizes the interpretation that is subsequently challenged by the husband.

The analysis of the origins of the argument in extract (4) demonstrates several aspects of the conversation analytic approach. First, it introduces another aspect of sequence organization: preference organization. Second, it shows one more time how the meaning of utterances is constituted along lines of sequential reasoning. An utterance in a turn at talk is not just what it says, but what it does in a particular sequential context. Third, the analysis illustrates that the methods by which participants make sense of their talk may be (re-)specified and (re-)negotiated in the course of the interaction. Finally, the discussion demonstrates some aspects of CA methodology discussed in the former section. The knowledge that first assessments invite a second assessment from its recipient stems from a collection study (Pomerantz, 1984). The interaction in extract (4) seems to contradict this pattern. Instead of continuing with a second assessment, the recipient responds with only an acknowledgement token. However, when this observation is combined with insight into the ways how preference organization operates, the interaction can be explained in terms of the very same mechanism. The analysis of a deviant case eventually provides a kind of second-order validation of the theory developed so far.

Extensions and Applications

The basic theoretical, analytical, and methodological framework of CA has been developed further into various domains and directions. Studies in the area of interaction and grammar explore the relationship between language structure, linguistic practices, and the organization of turn taking and of sequences in talk in interaction (Ochs *et al.*, 1996; Selting and Couper-Kuhlen, 2001; Ford *et al.*, 2002; Couper-Kuhlen and Ford, 2004).

The work of Charles Goodwin has given a major impetus to the study of the multimodal and embodied character of the organization of human action in talk in interaction – not only the role of gaze, gesture, and

body positioning, but also the use of tools and other features of the setting (Goodwin, 2000; see also the workplace studies in Heath and Luff, 2000). Goodwin (2003) provides a collection of CA studies of the ways in which people with one or another form of language impairment use various types of sequential and situational reasoning in ordinary communicative situations (see **Institutional Talk; Family Speak**).

Talk in institutional, professional, or work settings is also studied by describing how it is constrained or modified in comparison to conversational interaction (Drew and Heritage, 1992). The research in this area has frequently the shape of studying genres or activity types in a specific domain, e.g., the news interview (Clayman and Heritage, 2002), judicial interaction (Atkinson and Drew, 1979), emergency calls (Whalen and Zimmermann, 1990), meetings (Boden, 1994), telling good and bad news in clinical settings (Maynard, 2003), and gossip (Bergmann, 1993). The research here is sometimes called applied CA (see ten Have, 1999) (see **Institutional Talk**).

Wootton (1997) is an example of a CA study in the area of early language acquisition. The study of foreign language use in talk in interaction focuses on the organization of repair (see Schegloff, 2000b; Gardner and Wagner, 2004).

A primarily British group of social psychologists approaches typically psychological topics such as attitude, identity, and cognition from an interactional perspective, using CA as a central theoretical and methodological framework (Te Molder and Potter, 2004).

Journals that regularly publish CA papers are *Research on Language and Social Interaction*, *Discourse Studies*, *Human Studies*, *Journal of Pragmatics*, *Language in Society*, *Pragmatics*, and *Text*. Important centers of CA research are UCLA (Schegloff, Heritage, Clayman), UCSB (Lerner, Raymond), the University of Wisconsin (Maynard, Ford), the University of York (Drew, Local, Wootton), the University of Helsinki (Sorjonen), the University of Southern Denmark the Graduate School of Language and Communication (Wagner, Hougaard), the University of Bielefeld (Bergmann), and the Max Planck Institute Nijmegen, Language and Cognition Group (Stivers).

Discussion lists with CA-oriented discussion are the Language-use list, the Ethno-Hotline, the German *Gesprächsanalyse*-list, or the Danish MOVIN-list. The Ethno/CA News website of Paul ten Have announces conferences, publications, and other news.

Conversational Agents: Synthetic

J Cassell, Northwestern University, Evanston, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

Embodied conversational agents (ECAs) are virtual humans (often life-size) who are capable of carrying on conversations with real humans. These virtual humans may serve many functions, both practical and theoretical. In the practical vein, they may act as the interface to a computer so that instead of choosing commands on a menu, one can carry on a conversation.

Figure 1 shows an ECA named REA who acts as the interface to a database of houses in the Boston area. Rather than having to type in search terms, users can

tell REA what kind of property they are looking for, and REA will nod, reflect, and then find appropriate properties and describe them using a combination of descriptive hand gestures, head movements and spoken language.

ECAs can also serve as autonomously acting characters in video games. **Figure 2** shows an ECA that plays the role of a village leader that reacts to the soldier character played by the user. In this instance, the system is designed to teach Arabic in such a way that soldiers going into an unfamiliar culture learn appropriate body language as well as the necessary foreign words and phrases.

ECAs also allow linguists to model human linguistic behavior and to evaluate competing theories of

Figure 1 REA, the virtual realtor. Copyright MIT Media Lab.

Figure 2 The Tactical Language Training system: embodied conversational agents as autonomous game characters. Copyright by University of Southern California.

language use by observing them in action. **Figure 3** shows an ECA that gives directions by speaking, gesturing, and tracing a route on a map. This system has allowed researchers to discover the role of nonverbal behaviors, such as eye gaze and head nods, in grounding, or the establishment of information as shared between two participants.

In all of these cases, the embodied conversational agents are modeled on human face-to-face conversation and therefore get their meaning across by

employing not just text (as do regular computers with a mouse, keyboard, and screen) but also spoken speech with intonation, hand gesture, head movements, and facial expressions. Embodied conversational agents are defined by the following:

- The ability to recognize and respond to verbal and nonverbal input
- The ability to generate verbal and nonverbal output

Figure 3 MACK, the Multimodal Autonomous Conversational Kiosk. Copyright MIT Media Lab.

- The ability to deal with conversational functions, such as turn-taking, feedback, and repair mechanisms
- The ability to give signals that indicate the state of the conversation as well as to contribute new content to the discourse.

ECAs are inherently multidisciplinary endeavors, and they have piqued the interest of researchers in a number of different fields, from computer science (and its subfields of computer graphics, artificial intelligence, natural language processing, and human–computer interaction) to linguistics, psychology, and education. However, researchers have found themselves either relying on theories of human–human interaction and language use set forth by others or elaborating their own theories of these behaviors as a way of ensuring that their interfaces share the conversational skills of human users. Thus, for example, Lester *et al.*'s (2000) *COSMO* character refers to the objects in his environment using pronouns, descriptions, and/or pointing gestures according to a complex algorithm based on the linguistic theory of referential ambiguity. Wang *et al.*'s (2005) pedagogical agent and Walker *et al.*'s (1997) virtual actor both rely on Brown and Levinson's (1987) theory of politeness and language use. Cassell *et al.*'s (2000) Sam virtual child character supports children's development of literacy skills through modeling the use of nondeictic referring expressions, spatial locatives and temporal adverbs according to theories of children's acquisition. Poggi and Pelachaud (2000) base the facial expressions of their ECA on Austin's (1962) theory of performatives.

In the following sections, I outline some of the linguistic issues that are evoked by ECAs and how

these translate into conversational skills that allow humans to communicate with ECAs.

Sample Interaction with an ECA

REA is an ECA whose domain of expertise is real estate; she has access to a database of available properties for sale in Boston. She can display pictures of those properties and of their various rooms, and she can point out and discuss their salient features. Figure 4 is an excerpt from an actual interaction.

Conversational Properties

In addition to demonstrating the use of several conversational modalities, such as speech, hand gestures, and head movements, REA is engaging in some very subtle human-like behavior that demonstrates four properties of face-to-face conversation: (1) the distinction between conversational behaviors (e.g., eyebrow raises) and conversational functions (e.g., turn-taking), (2) the importance of timing among conversational behaviors (and the increasing cotemporality or synchrony among conversational participants), (3) the distinction between interactional and propositional functions of conversation, and (4) the planning of how to convey a concept with maximal efficiency. Each of these properties is described next with reference to REA and Mike's conversation.

Distinction between Function and Behavior

In order to allow humans and computers to converse successfully, one cannot hard-code conversational behaviors into the system. That is, for example, it does not work to tell the ECA to nod at the user

Mike approaches the projection screen. REA is currently turned side on and is gazing idly about. As Mike moves within range of the two cameras mounted above the screen, REA turns to face him and says:
 REA> Hello. How can I help you?
 MIKE> I'm looking to buy a place near MIT.
 REA *nods, indicating that she is following.*
 REA> I have a house to show you.
A picture of a house appears on-screen behind REA who blinks and looks at the house and then at Mike.
 REA> It's in Somerville.
 MIKE> Tell me about it.
 REA *briefly looks up and away while she plans what to say*
 REA> It's big.
 REA *makes an expansive gesture with her hands.*
 Mike *brings his hands up as if he is about to speak and so REA does not continue; instead waiting for him to speak.*
 MIKE> Tell me more about it
 REA> Sure thing. It has a nice garden.
 REA *sketches a curved gesture with her hands indicating that the garden extends along two sides of the house*
 MIKE> How far is it?
 REA> It is five minutes to the Porter Square T station.
 REA *makes it clear that it is five minutes on foot from the T station by making a walking gesture with her fingers*
 MIKE> How big is the house?
 REA> It has four bedrooms, three bathrooms. . .
 And the house tour continues.

Figure 4 Conversation with REA.

every time the user speaks because the ECA may not be able to nod if the head is already engaged in looking around the room. Instead, sometimes the ECA will want to signal that it is following by making agreement noises such as “uh huh.” Instead of hard-coding, the emphasis has to be on identifying the high level structural elements that make up a conversation. These elements are then described in terms of their role or function in the exchange. Typical discourse functions include conversation invitation, turn-taking, providing feedback, contrast and emphasis, and breaking away. Then, one can establish mappings between functions and behaviors. **Table 1** illustrates typical conversational functions and behaviors.

This is especially important for ECAs because particular behaviors, such as the raising of the eyebrows, can be employed in a variety of circumstances to produce different communicative effects, and the same communicative function may be realized through different sets of behaviors. The form we give to a particular discourse function depends on, among other things, current availability of modalities such as the face and the hands, type of conversation, cultural patterns, and personal style. Although such discourse functions have formed the object of many studies, particularly in the fields of ethnomethodology and conversational analysis, until the first ECAs, these observations had not been merged into one understanding of the interaction between

Table 1 Examples of conversational functions and their behavior realization

Communicative functions	Communicative behavior
<i>Initiation and termination</i>	
React to new person	Short glance at other
Break away from conversation	Glance around
Farewell	Look at other, head nod, wave
<i>Turn-taking</i>	
Give turn	Look, raise eyebrows (followed by silence)
Want turn	Raise hands into gesture space
Take turn	Glance away, start talking
<i>Feedback</i>	
Request feedback	Look at other, raise eyebrows
Give feedback	Look at other, nod head

From Cassell and Vilhjalmsson (1999).

different linguistic and nonverbal devices and the functions that they play in conversation.

The REA ECA generates speech, gesture, and facial expressions based on the current conversational state, the conversational function she is trying to convey, and the availability of her hands, head, and face to engage in the desired behavior. For example, when the user first approaches REA (‘user present’ state), she signals her openness to engage in conversation by looking at the user, smiling, and/or tossing her head. Once again, this approach comes directly from the conversational analysis literature on human–human conversation (Cassell, 2000). **Table 2** summarizes Rea’s current interactional output behaviors.

Importance of Timing

Behaviors that achieve a joint communicative goal occur in synchrony, and we assume that behaviors that cooccur carry meaning together. That is, the meaning of a nod is determined by where it occurs in an utterance, all the way down to the 200-millisecond scale (consider the difference between “you did a [great job]” (square brackets indicate the temporal extent of the nod) and “you did a [...] great job”). Thus, in the dialogue shown in **Figure 4**, REA says “it is five minutes from the Porter Square T station” at exactly the same time as she performs a walking gesture. If it occurred in another context, the same gesture could mean something quite different; if it occurred during silence, it could indicate Rea’s desire to take the turn. Although it has long been known that the most effortful part of a gesture cooccurs with the part of an utterance that receives prosodic stress (Kendon, 1972), it was not until researchers needed to generate gestures along with speech in an ECA that it was discovered that

Table 2 Output functions

State	Output function	Behaviors
User present	Open interaction	Look at user, smile, toss head
	Attend	Face user
	End of interaction	Turn away
	Greet	Wave, say "hello"
Rea speaking	Give turn	Relax hands, look at user, raise eyebrows
	Signoff	Wave, say "bye"
User speaking	Give feedback	Nod head, paraverbal ("hmm")
	Want turn	Look at user, raise hands
	Take Turn	Look at user, raise hands to begin gesturing, speak

it is the 'rhetic' (Halliday, 1967) or new contribution part of an utterance that receives the gesture.

One of the striking features of timing in conversation is the fact that during the course of a conversation, participants increasingly synchronize their behaviors to one another. Entrainment ensures that conversation will proceed efficiently (one of the functions that Brennan and Hulstien (1995) suggest are needed for more robust speech interfaces). REA cannot yet entrain her nonverbal behaviors to those of the listener. Human users, however, very quickly entrain to her, and begin to nod and turn their heads in synchrony with her within one or two conversational turns.

Division between Propositional and Interactional Functions

Some of the things that people say to one another move the conversation forward, whereas others simply regulate the conversational process. Propositional information corresponds to the content and includes meaningful speech as well as hand gestures that represent something. Interactional information regulates the conversational process and includes a range of nonverbal behaviors (quick head nods to indicate that one is following, or bringing one's hands to one's lap and turning to the listener to indicate that one is giving up the turn) as well as socio-centric speech ("huh?" and "do go on"). Both functions may be fulfilled by either verbal or nonverbal means. Thus, in the dialogue in **Figure 4**, Rea's nonverbal behaviors sometimes contribute propositions to the discourse, such as the gesture that indicates that the house in question is 5 minutes on foot from the T stop, and they sometimes regulate the interaction, such as the head nod that indicates that REA has understood Mike's utterance. For the most part, before the advent of ECAs, computational linguistics and work on dialogue systems concentrated on the propositional functions of language. Adding a body to dialogue systems, however, brought home the need for the 'phatic communion' (Malinowski, 1923) or social

aspects of conversational interaction between humans and machines.

Communicating Concepts with Maximal Efficiency

In e-mail, all of our communication goals must be translated into text (with the occasional emoticon). In face-to-face conversation, on the other hand, humans use every means at their disposal to communicate what they want to say. They use gestures to indicate things that may be difficult to represent in speech, and they depend on the ability to simultaneously use speech and gesture in order to communicate quickly. In this sense, face-to-face conversation allows us to be maximally efficient. In the dialogue reproduced in **Figure 4**, REA takes advantage of the hands' ability to represent spatial relations among objects and places by using her hands to indicate the shape of the garden (sketching a curved gesture around an imaginary house) while her speech gives a positive assessment of it ("It has a nice garden"). However, in order to produce this description, the ECA needs to know something about the representational properties of speech and gesture, something about how to merge simultaneous descriptions in two modalities, and something about what her listener does and does not already know about the house in question. These needs result in a new kind of computational architecture in which the planning of what the hands do and the planning of what language will do must be tightly coupled, and both must be linked to an information state module that keeps in mind the communicative goals and respective knowledge of both parties, as in **Figure 5** (Kopp *et al.*, 2005).

Research Issues

The field of ECAs is still in its infancy. Although ECAs are far more capable of engaging in human-like face-to-face conversation than they were even 10 years ago, nobody would yet mistake them for humans. In fact, the development of ECAs has allowed researchers to uncover a host of behaviors

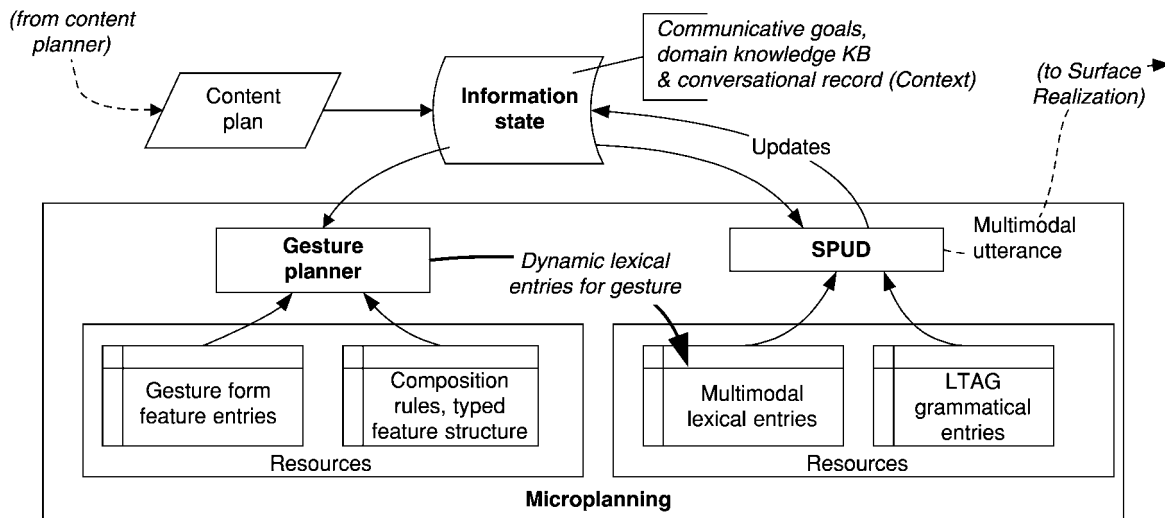

Figure 5 Multimodal microplanning.

that we take for granted, but that must be accounted for in a complete simulation of human communication. One large strand of current research on ECAs deals with the effect of emotion on verbal and non-verbal behavior in conversation (Andre *et al.*, 2000; Bui *et al.*, 2004; Chi *et al.*, 2000; Gratch and Marsella, 2004). Another examines personality and cultural differences and how these can be represented in ECAs (Loyall *et al.*, 2004; Trappl and Petta, 1997). Yet a higher-order concern is the social roles occupied by ECAs (Prendinger and Ishizuka, 2001), etiquette (Bickmore, 2004), and relationship building (Cassell and Bickmore, 2002). Finally, several researchers are constructing frameworks for evaluating the effects of ECAs on human-computer interaction (Ruttkay and Pelachaud, 2004). This issue is a thorny one. In this article we have spoken of ECAs as both practical and theoretical constructs, and yet the jury is still out on exactly how practical they are as interfaces to computing power. Nevertheless, ECAs have allowed us to analyze human behavior by synthesizing it in a way that previous tools did not allow.

Conversational Analytic Approaches to Culture

J Sidnell, University of Toronto, Toronto, Ontario, Canada

Introduction

Conversation analysis (hereafter CA) is an approach to the study of social interaction which emerged in the 1960s in the work of Harvey Sacks, Emanuel Schegloff, and Gail Jefferson. Early work in CA drew upon the sociologies of Goffman and Garfinkel but quickly took on a distinctive set of methods and analytic questions specifically adapted to its chosen subject matter – the organization of talk-in-interaction (see Heritage, 1984). Today CA is practiced within a vibrant, international community of researchers distributed across a range of fields including sociology and anthropology, linguistics, psychology, and communication studies. CA is not associated with a specific theoretical construct of culture. However, the findings of various studies within CA are suggestive of an approach to culture and society as these are typically understood in the social scientific literature.

CA Methods

What distinguishes CA most clearly from other approaches is its methodology. CA research is based

upon recordings (audio or audio-video) of human interaction (see Sacks, 1984 for the rationale). Analysis proceeds by unmotivated observation: that is, without looking for anything in particular (e.g., deictic particles, honorifics, talk about politics) the researcher attempts to isolate possible practices (relatively stable ways of performing actions). CA relies on unmotivated observation for the basic reason that – in working with conversational materials – it is not possible to adequately describe what one is looking for in advance of finding a set of instances (Schegloff, 1996a, 1997). Indeed, premature attempts to describe the phenomenon in the terms of some specialized vocabulary (e.g., linguistic, anthropological, sociological) often serve to obscure the very thing that is being investigated. A central point here is that a given practice need not be, and in fact rarely is, uniquely realized in a single form, i.e., there is no one-to-one mapping between forms and functions/practices. (This raises issues about the usefulness of traditional linguistic description in CA studies.) Take, for instance, other-initiated repair (Schegloff *et al.*, 1997 see **Conversation Analysis**). In English conversation, a wide range of formal devices may be used to initiate repair of a previous speaker's turn. These include 'open class' repair initiators such as 'huh?' (Drew, 1997); wh-words such as 'what?', 'who?', 'where?'; partial repeats, often with stress placed on

the specific target of the repair initiator (e.g., ‘You opened it?’); and ‘You mean X?’ formulations, as well as combinations of wh-word and partial repeat. So the initiation of repair is accomplished by a range of different formal devices (often engendering alternate trajectories of action). At the same time, the formal devices used for initiating repair of a prior speaker’s turn may also be used in quite other ways. ‘Huh?’, for example, also occurs as a tag while partial repeats may be used to confirm what another has just said. The absence of a one-to-one mapping thus goes both ways. The consequences of such a situation are various. As already noted, in terms of method it requires that analysis proceed not by searching out forms but instead practices, which, at the outset of the analysis, remain by necessity partially described. A more basic consequence has to do with placement: if a given form may serve as the vehicle for a number of different actions, how do participants in conversation figure out – overwhelmingly correctly – which action is being done with a given form? In an early paper Schegloff and Sacks (1973) described this in terms of a ‘placement problem’ and noted that a form such as ‘we::ll:’ can be understood, by participants and analysts alike, as a ‘possible preclosing’ on the basis of its placement at the recognizable end of talk on a topic. In the same paper they went on to formulate a powerful analytic question which summarizes the conversation analytic understanding of the relation between form, placement, and action – ‘why that now?’ The question, which has become the *sine qua non* of conversation analytic research, also points to the importance of working back and forth between the particular instance – and its embedding in some specific course of action – and the larger collection of which it is apart since the ‘that’ is definable only in terms of such a dynamical relation (see Schegloff, 1998).

Once a practice is identified, it is collected. The resulting collection then serves as the basis of an analysis. The advantage of working with a collection – is that it allows for the identification of ‘deviant’ cases – instances in which the practice does not (for whatever reason) follow its normal course – a ‘deviance’ to which participants themselves orient. Such deviant cases frequently reveal participants’ own orientations to the various contingencies involved in the execution of that practice – orientations which are typically unobservable in cases which conform to normative expectations and which are therefore literally unremarkable. In the context of an examination of practices for referring to persons, for instance, a collection of instances allows the analyst to distinguish cases in which just reference is being done from those in which something in addition to this

is being accomplished (for instance, in cases where a locally subsequent form is used in a locally initial position, e.g., a spouse returns home from work and is met immediately with ‘What did she say?’; see Schegloff, 1996b).

Collections allow, then, for the identification and description of practices of human interaction. A good deal of CA work is concerned to document and describe such practices – to add, as Goffman said, “another animal to the zoo.” But there is also a more basic issue at stake in conversation analytic research. CA aims to understand the mechanics which underlie and organize the wide range of practices which have been described. To this end, conversation analysts have introduced a number of important conceptual tools for understanding this underlying mechanics of interaction – for instance, the concepts of conditional relevance and preference (see Schegloff, 1968; Pomerantz, 1984). However, work in this area is still in its infancy. Thus, we have very good descriptions of how, on the one hand, person reference is done in conversation and how, on the other, place reference is done, but, at this point, very little sense of the ways in which both might be organized in relation to a more basic system of reference in conversation (though see Schegloff, 2000).

Implications for Concepts of Culture and Society

In his early work on conversational and other materials, Sacks developed an approach which eventually came to be known as ‘membership categorization analysis’ (MCA). MCA had clear links to the work done by ethnoscientists as well as ethnomethodological researches which examined the logic of categorization as manifested in people’s ordinary activities including conversation. In his well-known paper ‘On the analyzability of stories by children,’ Sacks (1974) examined a line from a child’s story, ‘the baby cried, the mommy picked it up,’ and attempted to explicate how it was that a listener knew intuitively that it was the **baby’s** mother (rather than some other ‘mother’) who picked the baby up. This he explained in terms of category-bound activities and rules for application (hearers’ and viewers’ maxims). MCA is essentially an examination of ordinary, vernacular logic and, as such, is quite clearly about ‘culture.’ Schegloff (2002) explains:

Sacks had proposed that a core element of vernacular culture was composed of common-sense ‘knowledge’ about members of the society and others organized by reference to types or categories of person, categories which were themselves organized into collections

of categories – such as [male, female], [Protestant, Catholic, Jew], [adult, child], [cat people, dog people], [Libra, Sagittarius, Leo], and so forth. Such collections were empirical objects; the grouping of categories into collections might be the case or not the case for some culture. The way I just exemplified the point was ‘correct,’ at least for American society and culture; it would have been for this culture incorrect to have proposed as a collection of categories [male, female, Sagittarius]; Sagittarius does not belong to that collection.

In the development of CA, MCA was superseded by the methods described above although its findings were to some extent incorporated into the analysis of sequence organization – specifically the analysis of person and place reference (see Schegloff, 1996b). Early work in MCA along with more recent developments in CA hold out the possibility of research into the culturally specific categorization techniques associated with different languages and cultures (see Schegloff, 2002).

‘Culture’ and Conversational Practices – The Possibility of Comparative Research

On one of the relatively few occasions that Sacks discussed ‘culture’ in his lectures he defined it as a ‘system for generating recognizable actions.’ This characterization fits well with methods and research agenda described above and points to the possibility of comparative studies. It suggests, that is, that cultures differ in terms of the actions (or practices) which they generate as recognizable. Most of the work in CA has examined English conversation and a question arises as to the extent to which the findings are generalizable to other languages, other cultures, or even contexts within the same culture.

‘A simplest systematics for the organization of turn-taking for conversation’ (Sacks, Schegloff & Jefferson, 1947) was a massively important paper within the development of CA. Not only did this paper provide one of the first systematic applications of CA methodology, it also described a very wide range of practices having to do with the construction of turns at talk, the distribution of opportunities to speak, and the basic properties of sequence organization and recipient design. A somewhat implicit claim of the paper was that the basics of the system described should account not just for English conversation but for conversation in general – regardless of language, culture, social situation, or whatever. Conversational turn taking, it was claimed, is locally managed, by and for the participants on a turn-by-turn basis. In that sense, conversation differs from ‘speech exchange systems’ in which turn taking is pre-allocated. Some anthropologists had advanced alternate descriptions of turn taking in the cultures

they had studied. Riesman (1974), for instance, described Antiguan creole conversations as ‘contrapuntal,’ even ‘anarchic’ and participants as having “no sense of interruption.” One of the great benefits of CA methodology is that it allows such claims to be tested empirically on actual conversational materials. Sidnell’s (2001) examination of turn taking in Caribbean creole conversations attempted to do just this and showed that Riesman’s claims are not supported by the data. On the contrary, the basic features of the system which organizes opportunities to speak in Caribbean creole conversations do not differ significantly from those described by Sacks *et al.* for American English. Such research suggests that conversational turn taking is not subject to a great deal of crosscultural variation (and, of course, there are a number of evolutionary reasons why this might be the case – see Goody, 1995).

While a good deal of conversational organization is not subject to cultural variation, there are also many practices which are specific to a group (defined in terms of culture or language). Stivers, for instance, in examining African-American English data, has found an apparently distinctive way of expressing agreement (and alignment) which involves making the same assertion or assessment as a previous speaker but using a completely different set of lexical items and idiomatic phrases to do so. In recent work, Levinson (2002) has examined practices for referring to persons in data from Rossell. He finds that although the system is basically the same as that described for English (in terms of the underlying preferences for recognition and minimization), it is ‘inflected’ by local taboos that disallow the use of names to refer to certain classes of relatives. The interactional problem created by such taboos is solved by the use of eyebrow flashes as well as gaze and manual points which ‘count as’ implicit references and therefore as taboo-compliant behavior.

Social Organization and Culture as an Organization of Conversational Practices

In addition to the comparative type of research described above, a number of ethnographers have used CA to describe a social group (or culture) as an organization of conversational practices. Marjorie Goodwin’s (1990) pioneering work on African-American children, for instance, analyzed the ways in which their social groups were built out of and realized within a set of practices of speaking. She found, for instance, that social groups were organized through the issuing and receipt of directives as well as the production of requests. More recently, Charles Goodwin (1994) has examined a range of professional settings (such as legal and archeological) in

terms of the conversational practices which constitute their practical work.

CA eschews top-down theorizing and it is, perhaps, for this reason that a CA approach to culture has not been either a priority or an outcome of research to date. However, conversation analytic work is strongly suggestive of an approach to culture and other topics of traditional social-scientific inquiry. If such notions are to be a part of conversation analytic research they will need to be grounded in the conversational materials which constitute the empirical base of this approach.

Cooperative Principle

K Lindblom, Stony Brook University, Stony Brook, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

The Principle Itself

In his William James Lectures at Harvard University in 1967, H. Paul Grice posited a general set of rules contributors to ordinary conversation were generally expected to follow. He named it the Cooperative Principle (CP), and formulated it as follows:

Make your conversational contribution such as is required, at the stage at which it occurs, by the accepted purpose or direction of the talk exchange in which you are engaged (Grice, 1989: 26).

At first glance, the Cooperative Principle may appear an idealistic representation of actual human communication. After all, as Grice himself has learned from his detractors, many believe “...even in the talk-exchanges of civilized people browbeating disputation and conversational sharp practices are far too common to be offenses against the fundamental

dictates of conversational practice.” Further, even if one discounts the tone of an exchange, “much of our talk exchange is too haphazard to be directed toward an end cooperative or otherwise” (Grice, 1989: 369).

However, Grice never intended his use of the word ‘cooperation’ to indicate an ideal view of communication. Rather, Grice was trying to describe how it happens that – despite the haphazard or even agonistic nature of much ordinary human communication – most discourse participants are quite capable of making themselves understood and capable of understanding most others in the course of their daily business.

What Counts as Cooperation?

Grice invites us to consider the following, quite unextraordinary exchange:

A: I am out of petrol.

B: There is a garage round the corner (Grice, 1989: 32).

Assuming A immediately proceeds to the garage, secures the petrol, and refills his car, we may describe B’s contribution as having been successful. By what rational process of thought was A so quickly able to come to the conclusion that the garage to which B refers would fulfill his need for petrol? Why did B’s utterance work? Grice’s answer: because A and B adhere to the Cooperative Principle of Discourse.

It is not hard to imagine that two friends sharing a ride would want to help each other through a minor crisis; thus, ‘cooperation’ in this scenario seems quite apt.

But imagine the exchange went this way instead:

A: I am out of petrol.

B: (sarcastically) How nice that you pay such close attention to important details.

In this second scenario, not only does B refuse to assist A in solving the problem, he uses the occasion to add to A’s conundrum an assault upon his character. Assuming A feels the sting, again B’s contribution has been successful. So how and why in this case has B’s contribution worked? How can such a sour response as B’s callous retort be considered ‘cooperative’? Again, Grice’s Cooperative Principle proves a useful answer. The explanation requires closer inspection of the strictness with which Grice uses the term.

The Cooperative Principle and the Maxims of Cooperative Discourse

Grice explicates his Cooperative Principle of Discourse in ‘Logic and Conversation,’ the paper originally presented at Harvard University in 1967, later

printed in Cole and Morgan (1975), and reprinted in a slightly revised version in Grice’s *Studies in the Way of Words* (1989). We cite from his final version as we assume this is the one he considered most complete. In the essay, Grice is careful to limit use of the CP for describing only talk exchanges that exhibit the following three specific characteristics:

1. The participants have some common immediate aim.
2. The contributions of the participants [are] dovetailed, mutually dependent.
3. There is some sort of understanding (often tacit) that, other things being equal, the transactions should continue in appropriate style unless both parties are agreeable that it should terminate (Grice, 1989: 29).

Though he is careful to limit the CP’s application to talk exchanges that exhibit these particular cooperative characteristics, this list should not be read as an admission of great limitation. For Grice finds that most talk exchanges **do** follow the CP because most talk exchanges do, in fact, exhibit the **cooperative** characteristics he outlines:

Our talk exchanges ... are characteristically, to some degree at least, cooperative efforts; and each participant recognizes in them, to some extent, a common purpose or set of purposes, or at least a mutually accepted direction (Grice, 1989: 26).

Grice identified the Cooperative Principle as a ‘super principle’ or a ‘supreme principle’ (1989: 368–369) that he generalized from four conversational ‘maxims’ he claimed discourse participants ordinarily follow. With a nod to Kant, Grice identifies the maxims as:

1. Quantity (give as much information as is required, and no more than is required)
2. Quality (do not say what is false or that for which you lack adequate evidence)
3. Relation (be relevant)
4. Manner (be clear, be orderly, and avoid ambiguity) (1989: 28).

Clear fulfillment of these maxims may be demonstrated in the following exchange:

A: Do you know where I can buy some petrol?

B: You can buy petrol at the garage right around the corner.

Let us assume that B is sincere and knowledgeable, and A finds the garage right away based upon B’s advice. It is the case then that B’s response to A’s question follows the maxims completely, giving exactly the right amount of information (quantity),

information for which B has the required evidence (quality), information that is directly connected to A's question (relevance), and information given in a fashion effectively and efficiently understood (manner).

But Grice knew that people do not always follow these maxims as they communicate. (What dull business conversation would be if they did!) Rather, interlocutors can fail to fulfill the maxims in a variety of ways, some mundane, some inadvertent, but others lead to what most consider the most powerful aspect of Grice's CP: conversational 'implicature.'

Failures to Fulfill Maxims and Implicature

Grice describes four ways in which maxims may go unfulfilled in ordinary conversation. The first three ways are fairly straight forward. One might **violate** or **infringe** a maxim. This infringement is often done with the intention of misleading; for example, one might say, 'Patricia was with a man last night' as a way of making Patricia's routine dinner out with her husband seem clandestine. One might **opt out**, making it clear that one refuses to cooperate in a conversation for some reason; for example, one may be legally bound not to provide information one has. Or, one might encounter a **clash** of maxims, facing the choice of violating one maxim or another. For example, one may not be able to give all of the information required (quantity) because one does not have adequate evidence for the information (quality).

Most interesting is the final possibility for the non-fulfillment of a maxim: **flouting** or **exploiting** a maxim for the purpose of implicating information (implicature). This case is the one in which even an apparently uncooperative response illustrates discursive or linguistic cooperation. Recall the examples with which this article was introduced.

A: I am out of petrol.

B: There is a garage round the corner.

In this instance, we may claim, that B – at first blush – appears to break the maxim of relation. For what does a garage have to do with petrol? Since drivers are aware that garages sell petrol, it is not long before A realizes that B has not broken the maxim of relation at all; it is, in fact, instantaneous. B's point is directly relevant. B is being cooperative in both the colloquial sense and the specialized sense Grice applies to the term. Grice's Cooperative Principle makes sense of the speed with which A is able to process the usefulness of B's contribution. A assumes B is following the maxims and would thus not mention the garage unless it had petrol.

In the next scenario, however, the exchange, and thus the rational process by which A makes sense of B's contribution, is markedly different:

A: I am out of petrol.

B: (sarcastically) How nice that you pay such close attention to important details.

In this instance, B flouts the maxim of quality by stating as true something for which he has specific and immediate evidence is untrue. One likely implication of B's remark is that A is an idiot for not paying attention to such an important detail as having enough petrol in the car. If A feels the sting of B's remark, A and B have exhibited discursive cooperation that resulted in an implicature directed to A from B (see **Maxims and Flouting**).

While one example hardly illustrates so many cases, Grice works out a number of possible forms of implicature: irony, metaphor, meiosis (understatement), hyperbole, social censure, deliberate ambiguity, and deliberate obscurity (for example, if one is trying to keep a secret from the children). In all of these cases, maxims are broken and the breaks result in specific information implied to and understood by the receiver of the utterance.

The power of the conversational maxims to describe rational processes by which speakers and hearers make sense of each other's utterances have energized many scholars of language and conversation across many fields. But, as the introduction to this article makes clear, the Cooperative Principle has not been free from serious critique.

Major Critiques of the Cooperative Principle

Problems with the Term 'Cooperation'

Despite the care with which he used the term "cooperation," Grice is regularly accused of promulgating a theory that assumes too friendly a spirit of communicative interaction among people. This charge is most commonly made in work outside of Grice's own field of linguistic philosophy. In effect, these detractors claim Grice is just too nice.

For example, Tannen (1986) claims that Grice's maxims of cooperative discourse can't apply to "real conversations" because in conversation "we wouldn't want to simply blurt out what we mean, because we're judging the needs for involvement and independence" (1986: 34–45). Tannen assumes that Grice's maxims are prescriptions that conversations must follow strictly in order to be considered cooperative. Cameron (1985) makes a similar case, taking issue with Grice's application of the term 'cooperation' to all discourse.

Cameron is quite correct in her claim that – at least in the colloquial sense of the term – assumptions regarding the appropriateness of ‘cooperative’ behavior have dogged women for centuries. But Cameron demonstrates a reductive view of Grice’s use of the term ‘cooperation’ when she describes Grice’s CP as an ‘inflexible’ and ‘unproductive’ apparatus that provides yet another way for both ‘chauvinists and feminists’ to believe that ‘whereas men compete in competition, women use co-operative strategies’ (1985: 40–41). Grice’s version of cooperation is more flexible and less dogmatic than these critics assume.

Others have gone so far as to claim Grice **advocated** cooperation among conversational participants, believing Grice prescribed cooperation as the most effective way of engaging in meaningful communication with others.

Cooper (1982), interested in applying Grice to theories of written composition, claims that Grice advocates cooperation because

what enables conversation to proceed is an underlying assumption that we as conversants have purposes for conversing and that we recognize that these purposes are more likely to be fulfilled if we cooperate (1982: 112).

The notion that discourse participants cooperate with each other and that they do so out of a mutual benevolence is a misreading of Grice’s position on cooperative discourse; but it is one that persists.

Grice himself acknowledged the difficulty some have had interpreting his use of ‘cooperation.’ As a final chapter to his 1989 book, Grice wrote a ‘Retrospective Epilogue’ in which he considered criticism his theories had engendered. It has already been related that here Grice acknowledged that his theory suffers from a perceived naïveté. To combat the criticism, Grice adds useful information about what counts as cooperative in discourse. First, he reminds readers of the sort of utterances he seeks to elucidate: voluntary talk exchanges that require some form of “collaboration in achieving exchange of information or the institution of decisions.” And, he points out that within exchanges intended to produce information or determine decisions, cooperation “may coexist with a high degree of reserve, hostility, and chicanery and with a high degree of diversity in the motivations underlying quite meager common objectives” (Grice, 1989: 369). Even as adversarial an exchange as a hostile courtroom cross-examination would at least simulate adherence to the CP.

To further explain the sort of cooperation to which Grice refers, it might help to borrow a term from classical rhetoric. The ancient Greeks used the term

‘Nomos’ to indicate cultural practices that defined a group of people. Two closely related connotations of the term are useful for the present discussion: (1) ‘the mores’ of a given collective (Ostwald, 1969: 33); and, (2) customs “which are generally observed by those among whom they prevail” (1969: 36). Nomos is not necessarily an explicit, prescribed set of conventions, but rather a set of conventions that are brought into existence by the very fact that people ordinarily follow them, perhaps without even realizing they are following a set of conventions. When American youths visit Europe, the locals can spot them in an instant by their footwear; but, in the United States, sneakers are simply what young people ordinarily wear.

Nomos applied to conversation, then, is a set of conventions, or rules (or maxims) for talk according to which a group of people ordinarily makes meaning. In the maxims, Grice believes he has found universal conventions that all people may regularly follow in their meaning-making talk exchanges. In order for such a set of conventions to function, a certain degree of at least tacit assent to those conventions is necessary. Thus, the term ‘cooperation’ is quite apt.

The crucial subtlety of Grice’s theory is this: interlocutors do not necessarily cooperate with each other; they cooperate with a set of conventions that allows each interlocutor to produce approximate enough meanings for communication to work. This form of cooperation is not necessarily benevolent at all; even the bitterest of verbal fights require linguistic cooperation to work.

The aim for Gricean conversation analysis – and thus the CP and the maxims – is not to advocate benevolent cooperation, but to prove the rationality of conversation. “...observance [of the maxims] promotes and their violation [except in the case of implicature] dispromotes conversational rationality” (Grice, 1989: 370).

Although many have claimed Grice’s writing on the CP is ambiguous and is on occasion inconsistent with terminology, this should not be said of Grice’s measured use of the term ‘cooperation.’

Precise readings of Grice’s writing on cooperation demonstrate that he rarely, if ever, describes interlocutors as **being** cooperative. Rather, he claims that interlocutors’ contributions to conversation **are** cooperative. The contributions are uttered in cooperation with a set of conventions for producing meaning. In this sense, we might think of a pair of interlocutors as each operating according to the dictates of a set of conventions (the maxims) and thus they are ‘co/operators’: two operators of discourse operating at once.

Consider also, Grice's use of the term 'dovetailed' in describing the state of cooperative contributions to conversation (1989: 29). Dovetailed elements are placed within very close proximity to each other, maintaining the integrity of each separate element, but creating a stronger whole. Utterances remain utterances, but conversations take flight, implicating new meaning for hearers and speakers.

Problems with the Maxims: The Haphazardness of Communication and the Specificity of Maxims

The second major critique of the Cooperative Principle has been a topic of spirited discussion among linguistic philosophers since Grice first proposed it. Grice himself identifies the problem as resulting from the thought that communication is simply too "haphazard" to be described accurately as having a cooperative end. Some forms of communication are not appropriately described by the CP. For example, as Grice puts it, "Chitchat goes nowhere, unless making the time pass is a journey" (1989: 369).

Grice suggests the problem is two-fold. First, he agrees with critics that the maxims appear less "coordinate" than he would prefer. The maxim of quality appears in some ways more definitive of information than the other maxims. And, the maxims are not independent enough: relevance, as will be shown, has been often regarded as containing the essence of the other maxims. Second, Grice's selection of cooperation as the "supreme Conversational Principle" underpinning the rationalizing operations of implicature remains, to say the least, not generally accepted (1989: 371).

In his 'Conversational maxims and rationality' Kasher (1976), claims that cooperation is not a principle that accounts for all information conveyed by implicature because cooperation may be "contrary to [a speaker's] interest" (1976: 241). Kasher offers the following example: Man A. is asked by Man B. "Who is going to marry your sister?" Man A., who knows the proper name of the intended, replies, "A peacock dealer." Man A.'s reply, Kasher points out, does not satisfy the demands of full cooperation, and the CP, claims Kasher, cannot account for a situation in which there is no cooperation. As an alternative explanation for the operation of conversational implicature, Kasher poses the "Rationalization Principle," which stems from the idea that Relevance (one of Grice's maxims) is the only necessary element to explain a talk exchange. In a later work, Kasher renames his principle "the principle of rational coordination," which states: "Given a desired basic purpose, the ideal speaker chooses that linguistic action which, he believes, most effectively and at least cost attains that purpose" (Kasher, 1977). Kasher's well

known critique thus began what has become 'Relevance Theory,' which is at its base a refinement of Grice's earlier work (*see Relevance Theory*). (See below for references to other work on Relevance.)

Though in his final work he admitted some misgivings and offered minor refinements of his maxims of cooperative discourse, Grice, up until his death in 1988, defended his selection of the Cooperative Principle as the 'supreme principle.'

Scholarship Influenced by the Cooperative Principle

Though critiques of the CP remain unresolved – and perhaps they always will be – there is nevertheless no denying that Grice's CP has had a dramatic influence on discourse studies across disciplines. The CP can probably not be considered definitive, but there is no denying it has proven quite generative.

Because Grice's Cooperative Principle has such cross-disciplinary appeal, any survey of work influenced by it is almost certainly incomplete. The sketch here is intended to acquaint the reader with some applications of major importance and to give readers a richer understanding of the depth and breadth of the influence Grice has had. (For more citations and commentary on work influenced by Grice's CP, see Lindblom, 2001.)

Grammar

Grammarians frequently view literal or sentence meaning as more important than any individual's intended meaning in making an utterance. Thus Chomsky, for example, has critiqued Grice's CP for being unprincipled (1975: 112) and has complained that Grice's approach to language study is behaviorist due to his focus on utterer's intention (Suppes, 1986: 121). Other grammarians influenced by Chomsky have used similar logic to critique the CP as too concerned with context.

Suppes, whose essay is an excellent synthesis of grammar studies using Grice, argues that these grammarians assume an even more closely rule-bound language governance, making their claims essentialist. Further, he argues, that Grice's CP is useful precisely because it is so context dependent. Chomsky's positivism is not an issue in a Gricean analysis because Grice's work "bring[s] out the importance of context" (Suppes, 1986: 124).

Neo-Gricean Pragmatics

Grice's influence is most apparent in a branch of linguistic study that has become known among some as Neo-Gricean pragmatics. Scholars in this

field have greatly revised Grice's maxims of cooperative discourse in a variety of interesting ways, but they have maintained the basic direction of Grice's work, especially in regard to the concept of conversational implicature. Huang (1991) usefully surveys a great deal of scholarship from well known scholars in this area, including Atlas, Levinson, Sperber and Wilson, Leech, and Horn (*see Neo-Gricean Pragmatics*).

As mentioned previously, Kasher developed a specific focus on one of Grice's maxims, thus establishing the field of Relevance Theory. Sperber and Wilson have also generated an important Relevance Theory, theirs influenced by Fodor's theory of cognitive modularity. According to Huang, Sperber and Wilson believe "one is always maximizing the informational value of contextual stimuli to interpret the utterance in a way which is most consistent with the Principle of Relevance" (Huang, 1991: 303). Along with texts by Kasher and Sperber and Wilson, important developments in Relevance Theory may also be found in Grandy and Warner (1986) and Tsohatzidis (1994).

More recently, a special issue of *Journal of Pragmatics* has focused exclusively on Gricean themes in pragmatic analysis. Although he resists the notion of a school of 'Neo-Gricean' approaches, the journal editor has nevertheless gathered a collection of papers that illustrates that Grice's CP and maxims are ideas that "shook the world of language study in the past century, and continue to move and inspire today's research" (Mey, 2002: 911). The special issue includes essays focused on social roles in Japan, maxim confluence among multi-lingual code-switchers, academic writing, and other current approaches to Gricean pragmatics.

The CP is not only applicable across cultures, it is also possible to use Gricean analysis to examine a 'theme' in discourse. For example, much interesting work is underway in the pragmatics of humor (for example, Attardo, 2003).

Politeness Theory

Politeness theorists use Grice's CP specifically to examine the ways in which maxims are exploited to indicate some special status of the hearer. For example, a lawyer would answer a judge, "Yes, your honor." The 'your honor' breaks the maxims of quantity – as surely the judge is aware of her title – but including the words 'your honor' implies the speaker's understanding that the judge holds a greater position of authority.

For a valuable survey of Politeness Theories, see Fraser (1990). In this piece Fraser examines politeness theories posited by Lakoff and by Leech, and he explains that both of these theories rely heavily on

Grice's CP, though Lakoff reduces the maxims by two and Leech increases the number by six. The most influential Politeness Theory was developed by Brown and Levinson (1987).

Brown and Levinson's work is primarily influenced by Goffman, but they also claim "Grice's theory of conversational implicature and the framework of the maxims that give rise to such implicatures is essentially correct" (1987: 3). Goffman's influence may be seen in Brown and Levinson's concentration on the concept of 'face wants.' Their politeness theory examines the ways in which speakers and hearers use conversational implicature to fulfill the 'face wants' of higher-status participants in conversation. Like the CP itself, Politeness Theory is certainly not free from critique, but it has resulted in fascinating analysis and has generated much spirited debate (*see Face; Politeness*).

Question Processing

Several works in the area of question processing have developed from Grice's Cooperative Principle. Questions and questioning patterns can result in implicatures regarding politeness, status, and authority, and they operate according to conventions that many have build upon Grice's maxims. Singer provides a useful assessment of the study of question processing in all of its stages: question encoding, question categories, selection of answering strategies, memory search, comparison, and response (1990: 261). He identifies 'response' as the category for which Grice's CP is the most powerful.

Most interesting in 'response' is Lehnert's theory of secondary questions. According to Singer, "If asked 'Are there oil wells in Manitoba?' a simple 'no' would appear rather blunt. Instead, in keeping with Grice's 'maxim of quantity' and Lehnert's theory of secondary questions, it is more appropriate to hypothesize the next logical question and answer, 'There are a few, but there is not much oil east of Saskatchewan.'" (Singer, 1990: 273).

Gender Studies

Though above we single out some scholarship in gender studies for applying superficial accounts of the CP, there is excellent scholarship in the field that has used Grice's CP and maxims to examine behavioral and status differences between women and men. Brown, using the Politeness Theory she developed with Levinson, has used Grice to examine the sociopolitical situations of women in non-Western cultures (1990). Rundquist and Michell have looked at men's and women's use of conversational strategies in western culture.

Rundquist uses Grice to confront the “popular belief that women’s speech is more indirect than men’s” (1992: 431). She finds that men more frequently than women flout maxims to implicate information. Some of the purposes she identifies for which men tend to implicate information include to “give direction to their children,” to “put themselves down as well as to tease others,” “to be humorous,” “to show themselves off to their best advantage in conversation,” and perhaps most significantly for a study of gender, “to avoid direct confrontation” (Rundquist, 1992: 447). Michell (1984) questions if women often flout maxims to implicate information. She determines that women are far more likely to simply lie to protect themselves from verbal and physical abuse in a misogynist culture. For example, imagine a woman missed a meeting because she had painful menstrual cramps and because she had an important report to finish. This woman would be far more likely to claim she missed the meeting because of the report, leaving out the mention of cramps, even if the report was not even close to being the primary reason for her absence; her omission is an opting out, not an implicature (Michell, 1984: 376).

Teacher Research and Pedagogy

Studies in teacher research have approached Grice’s Cooperative Principle for two important purposes: (1) to examine the discourse of the classroom situation; and (2) to establish effective pedagogical strategies.

Three valuable works serving the first purpose may be found in Edwards and Mercer (1987), Kleifgen (1990), and McCarthy (1987). The first two works focus closely on the ways in which the educational scenario highlights the need for listeners to fill in propositions implicated by speakers. Edwards and Mercer examine the ways in which children become more and more proficient in these skills through their educational training. Kleifgen suggests that teachers should look for the points in classroom discourse when students begin to predict the outcomes of teachers’ questions so quickly that it is clear the students are ready to move on to a higher level of difficulty.

McCarthy’s essay – probably the finest treatment of the CP from a pedagogy scholar – traces the development of a college student as he writes for his composition, cell biology, and poetry classes. Examining both the student’s written assignments and the teachers’ detailed responses to them, McCarthy uses Grice’s CP to determine what is required for this student to cooperate as a writer in each class and whether or not he was successful. In McCarthy’s judgment, the student was successful as a student

because he was able to determine “what counted as ‘cooperation’” in each of his classes (1987: 249). Thus, McCarthy uses the CP in a flexible, context specific manner consistent with Grice’s own descriptions of it.

Other scholars with an interest in writing instruction have used Grice for productive ends. Though they are too likely to read Grice’s CP as describing a benevolent, cooperative relationship between writer and reader, Cooper (1982; 1984) and Lovejoy (1987) have used the CP to positive effect in college writing classes. Lovejoy’s very practical revising template using the maxims is especially useful for college students learning to write more sophisticated texts.

Professors of literature have also found Grice’s CP of use in articulating abstract themes from literature. Pratt’s (1977) work is probably the best known, but for a fascinating reading of Beckett’s *Waiting for Godot* using Gricean analysis, see Gautam and Sharma (1986).

Conclusion

A cross-disciplinary examination of how Grice’s Cooperative Principle has been put into practice clearly indicates that the CP has had tremendous appeal and influence. It is precisely the CP’s flexibility and context-dependent nature that makes it of such broad value. However, that same flexibility and context-dependence has also generated a fair number of critiques that cite lack of specificity and a too-relativistic application to discourse. Thus, it seems, the CP’s strength is also its weakness. Certainly a great diversity of scholars have found the Cooperative Principle of Discourse and its attendant Maxims of Conversational Cooperation useful as analytical tools toward a variety of ends. It is doubtful, however, that the notion of ‘cooperation’ among discourse participants will ever be universally accepted.

Critical Applied Linguistics

A Pennycook, University of Technology,
Sydney, Australia

© 2006 Elsevier Ltd. All rights reserved.

Doing Applied Linguistics Critically

Although the term 'critical applied linguistics' is relatively recent (see Pennycook, 2001), it draws on a far longer history of critical work in related domains, work that can be traced back at least to the early part of the 20th century. In this first section, however, I will present critical applied linguistics in its contemporary forms by providing a brief summary of interlocking domains of applied linguistic work that operate under an explicit critical label, including critical discourse analysis, critical literacy, critical

pedagogy, or critical language testing, as well as both areas that have developed a critical focus without using the label, such as critical approaches to translation or language policy, and those that have used alternative critical banners, such as feminism, antiracism, and so on (Table 1). By and large, this work can be characterized as dealing with applied linguistic concerns (broadly defined) from a perspective that is always mindful of the interrelated concerns (adapting Janks, 2000) of dominion (the contingent and contextual effects of power), disparity (inequality and the need for access), difference (engaging with diversity), and desire (understanding how identity and agency are related). Thus, in their discussion of critical literacy, Luke and Freebody suggest that "although critical literacy does not stand for a unitary approach,

Table 1 Domains of critical applied linguistics

Domains	Key works/authors	Orientation
Critical applied linguistics	Pennycook A (2001). <i>Critical applied linguistics: a critical introduction</i> . Mahwah, NJ: Lawrence Erlbaum	"Critical applied linguistics . . . is more than just a critical dimension added on to applied linguistics: It involves a constant skepticism, a constant questioning of the normative assumptions of applied linguistics. It demands a restive problematization of the givens of applied linguistics, and presents a way of doing applied linguistics that seeks to connect it to questions of gender, class, sexuality, race, ethnicity, culture, identity, politics, ideology and discourse" (Pennycook, 2001: 10)
Critical discourse analysis	Fairclough N (1995). <i>Critical discourse analysis</i> . London: Longman.	CDA "aims to systematically explore often opaque relationships of causality and determination between (a) discursive practices, events and texts, and (b) wider social and cultural structures, relations and processes; to investigate how such practices, events and texts arise out of and are ideologically shaped by relations of power and struggles over power" Fairclough (1995: 132).
Critical literacy	Muspratt S, Luke S A & Freebody P (eds.) (1997). <i>Constructing critical literacies: teaching and learning textual practice</i> . St Leonards, NSW: Allen & Unwin Clark R & Ivanic R (1997). <i>The politics of writing</i> . London: Routledge	CL "marks out a coalition of educational interests committed to engaging with the possibilities that the technologies of writing and other modes of inscription offer for social change, cultural diversity, economic equity, and political enfranchisement" (Luke and Freebody, 1997: 1).
Critical language awareness	Fairclough N (ed.) (1992). <i>Critical language awareness</i> London: Longman.	"People cannot be effective citizens in a democratic society if their education cuts them off from critical consciousness of key elements within their physical or social environment. If we are committed to education establishing resources for citizenship, critical awareness of the language practices of one's speech community is an entitlement" (Fairclough, 1992: 6).
Critical approaches to translation	Venuti L (1997). <i>The scandals of translation: towards an ethics of difference</i> . London: Routledge.	"To shake the regime of English, a translator must be strategic both in selecting foreign texts and in developing discourses to translate them. Foreign texts can be chosen to redress patterns of unequal cultural exchange and to restore foreign literatures excluded by the standard dialect, by literary canons, or by ethnic stereotypes" (Venuti, 1997: 10–11)
Critical approaches to language policy	Phillipson R (1992). <i>Linguistic imperialism</i> . Oxford: Oxford University Press. Ricento (ed.) <i>Ideology, politics and language policies: focus on English</i> . Amsterdam: John Benjamins. 9–24.	Phillipson's work "places English squarely in the center of the fundamental sociopolitical processes of imperialism, neo-colonialism, and global economic restructuring" (Tollefson, 2000: 13). Language policy and planning "must deal with issues of language behavior and identity, and so must be responsive to developments in discourse analysis, ethnography, and critical social theory" (Ricento, 2000: 22–23).
Critical sociolinguistics	Williams G (1992). <i>Sociolinguistics: a sociological critique</i> . London: Routledge. Wodak R (1996). <i>Disorders of discourse</i> . London: Longman.	"Discourse sociolinguistics, like critical linguistics . . . aims at de-mystifying . . . disorders [in discourse] . . . in the two domains of discourse, in actual language use in institutions and in the intersection of institution and everyday life. In both cases, we will also pose the question of possible changes" (Wodak, 1996: 3).
Critical approaches to second language education	Canagarajah S (1999). <i>Resisting linguistic imperialism in English teaching</i> . Oxford: Oxford University Press. Norton B (2000). <i>Identity and language learning: gender, ethnicity and educational change</i> . Harlow: Longman/Pearson.	"It is important to understand the extent to which classroom resistance may play a significant role in larger transformations in the social sphere" (Canagarajah, 1999: 196). We need a "concept of the language learner as having a complex social identity that must be understood with reference to large and frequently inequitable social structures which are reproduced in day-to-day social interactions" (Norton Peirce, 1995: 579).
Critical pedagogy and second language education	Morgan B (1998). <i>The ESL classroom: teaching, critical practice and community development</i> . Toronto: University of Toronto Press.	"ESL teachers, through both their responses and their silence, define what is appropriate and what might be possible in a new country" (Morgan, 1998: 20).

Continued

Table 1 Continued

Domains	Key works/authors	Orientation
	Norton B & Toohey K (eds.) (2004). <i>Critical pedagogies and language learning</i> . Cambridge: Cambridge University Press.	"Advocates of critical approaches to second language teaching are interested in relationships between language learning and social change" (Norton and Toohey, 2004: 1).
Critical English for academic purposes	Benesch S (2001). <i>Critical English for academic purposes: theory, politics, and practice</i> . Mahwah, NJ: Lawrence Erlbaum.	"The overarching goal of critical EAP is to help students perform well in their academic courses while encouraging them to question and shape the education they are being offered" (Benesch, 2001: xvii)
Critical bilingualism	Walsh C (1991). <i>Pedagogy and the struggle for voice: issues of language, power, and schooling for Puerto Ricans</i> . Toronto: OISE Press.	CB implies "the ability to not just speak two languages, but to be conscious of the sociocultural, political, and ideological contexts in which the languages (and therefore the speakers) are positioned and function, and the multiple meanings that are fostered in each" (Walsh, 1991: 127)
Critical multiculturalism	Kubota R (2004). 'Critical multiculturalism and second language education.' In Norton B & Toohey K (eds.) <i>Critical pedagogies and language learning</i> . Cambridge: Cambridge University Press. 30–52.	CM "critically examines how inequality and injustice are produced and perpetuated in relation to power and privilege" (Kubota, 2004: 37) exploring "a critical understanding of culture" (Kubota, 2004: 38), and involving all students "in critical inquiry into how taken-for-granted knowledge, such as history, geography, and lives of other people, is produced, legitimated, and contested in power struggles" (Kubota, 2004: 40).
Critical classroom discourse analysis	Kumaravadivelu B (1999). 'Critical classroom discourse analysis.' <i>TESOL Quarterly</i> 33(3), 453–484.	CCDA draws on critical ethnography as a research tool, has "a transformative function" and "seeks to play a reflective role, enabling practitioners to reflect on and cope with sociocultural and sociopolitical structures that directly or indirectly shape the character and content of classroom discourse" (Kumaravadivelu, 1999: 473).
Critical language testing	Shohamy E (2001). <i>The power of tests: a critical perspective on the uses of language tests</i> . London: Longman.	CLT "implies the need to develop critical strategies to examine the uses and consequences of tests, to monitor their power, minimize their detrimental force, reveal the misuses, and empower the test takers" (Shohamy, 2001: 131).

it marks out a coalition of educational interests committed to engaging with the possibilities that the technologies of writing and other modes of inscription offer for social change, cultural diversity, economic equity, and political enfranchisement" (Luke and Freebody, 1997: 1).

Probably the best known work has been in the related areas of critical discourse analysis (CDA) and critical literacy, which share a concern to understand texts and practices of reading and writing in relationship to questions of power, equity, diversity, and change. Whether as a mode of research (analyses of texts or of literacy contexts) or as a mode of pedagogy (developing abilities to engage in critical text analysis), these approaches to textual analysis are concerned with relations among texts, discourses, ideologies, and the wider social and political order. Norman Fairclough, whose approach to CDA has achieved considerable popularity, explains that critical discourse analysis "aims to systematically explore often opaque relationships of causality and determination between (a) discursive practices, events and texts, and (b) wider social and cultural structures, relations and processes; to

investigate how such practices, events and texts arise out of and are ideologically shaped by relations of power and struggles over power" (Fairclough, 1995: 132). CDA and critical literacy have also been combined under the rubric of critical language awareness, since the aim of this work is to "empower learners by providing them with a critical analytical framework to help them reflect on their own language experiences and practices and on the language practices of others in the institutions of which they are a part and in the wider society within which they live" (Clark and Ivanic, 1997: 217).

A textual domain that has received much less attention is critical work in translation studies (a minority focus within applied linguistics itself). And yet, it is clear that a focus on dominion, disparity, difference, and desire underpins various forms of work, from studies of how particular translations can clearly be read as ideological formations (see Hatim and Mason, 1997) to studies of the role translation has played within different historical formations, from colonialism to globalization. Indeed, Venuti's approach to translation takes the position that to "shake the regime of English,

a translator must be strategic both in selecting foreign texts and in developing discourses to translate them. Foreign texts can be chosen to redress patterns of unequal cultural exchange and to restore foreign literatures excluded by the standard dialect, by literary canons, or by ethnic stereotypes" (Ventui, 1997: 10–11). Such work surely needs to be included within critical applied linguistics since it is based on an antihegemonic stance, locates itself within a view of language politics, makes an ethics of difference central, and tries, in its practice, to move toward change.

Also focusing on the global hegemony of English and the need to promote diversity is critical work in language policy and planning. While much work in language policy has been remarkable for its political quietism, debates around the global spread of English and the destruction of the world's linguistic diversity have developed a clearer critical agenda. Central here has been Phillipson's (1992) accusation of (English) linguistic imperialism, and his argument that English has been spread for the economic and political advantage of the core English-speaking nations. As Tollefson (2000) explains, Phillipson's work differs markedly from mainstream sociolinguistic work focusing on the global spread of English since he "focuses on the unequal distribution of benefits from the spread of English." Rather than viewing the spread of English in positive terms and focusing on descriptions of varieties of English, Phillipson's work "places English squarely in the center of the fundamental socio-political processes of imperialism, neocolonialism, and global economic restructuring" (Tollefson, 2000: 13). These concerns have then been allied with accusations of linguistic genocide and the need for linguistic human rights to protect the global diversity of languages (Skutnabb-Kangas, 2000). While these arguments have raised considerable debate, especially in relation to the need to understand how the global position of English is resisted and appropriated (Canagarajah, 1999; Pennycook, 2001), the focus on the politics of language and an agenda for change clearly provide a significant critical dimension to any understanding of the dominance of English and continued linguistic diversity.

Sociolinguistics more generally has also been taken to task for lacking a critical dimension, Mey calling for a "critical sociolinguistics" that can "establish a connection between people's place in the societal hierarchy, and the linguistic and other kinds of oppression that they are subjected to at different levels" (Mey, 1985: 342). While sociolinguistics would appear to have the tools to deal with questions of language and power, the argument here is that ways in which power operates in relation to class,

gender, or race have not received adequate attention or a focus on possibilities of intervention. Some of these challenges have been taken up in work on language use in workplace settings, which aims not just to describe inequitable practices but also to change them. Wodak's study of hospital encounters, for example, looks not only at the ways in which "doctors exercise power over their patients" (Wodak, 1996: 170) but also at ways of intervening in this relationship. Other work in this domain has looked at language use in a range of institutional settings – language and the law, language in medical settings, language and education – to reveal how the complex relations between institutional power and the larger social context create inequitable but potentially changeable relations through language.

Critical approaches to language education – sometimes under the rubric of critical pedagogy – have had fairly wide coverage. As Norton and Toohey explain, "advocates of critical approaches to second language teaching are interested in relationships between language learning and social change" (Norton and Toohey, 2004: 1). As with the related domains of critical literacy and discourse analysis, critical approaches to language education can be viewed as both a critical research enterprise and as a domain of practice. Significant research in the first category would include work such as Canagarajah's critical ethnographies of 'periphery' students' and teachers' forms of resistance to English and English teaching methods: "it is important to understand the extent to which classroom resistance may play a significant role in larger transformations in the social sphere" (Canagarajah, 1999: 96); and Bonny Norton's work on ways in which gender, power and identity are interlinked in the process of language learning (Norton, 2000). Morgan (1998) and many others (see Norton and Toohey, 2004; Pennycook, 1999), meanwhile, look more directly at how forms of critical pedagogy in second language classrooms may bring about change.

Interrelated fields of research and practice have also emerged here, including Benesch's *Critical English for academic purposes*, which "assumes that current conditions should be interrogated in the interests of greater equity and democratic participation in and out of educational institutions" (Benesch, 2001: 64); Walsh's notion of critical bilingualism, which she explains as "the ability to not just speak two languages, but to be conscious of the socio-cultural, political, and ideological contexts in which the languages (and therefore the speakers) are positioned and function, and the multiple meanings that are fostered in each" (Walsh, 1991: 127); Kubota's argument for critical multiculturalism, which

“critically examines how inequality and injustice are produced and perpetuated in relation to power and privilege” (Kubota, 2004: 37) by focusing directly on issues of racism – on “collective, rather than individual, oppression” (Kubota, 2004: 37) – by problematizing, rather than presupposing difference, exploring “a critical understanding of culture” (Kubota, 2004: 38), and involving all students “in critical inquiry into how taken-for-granted knowledge, such as history, geography, and lives of other people, is produced, legitimated, and contested in power struggles” (Kubota, 2004: 40); and Kumaravadivelu’s critical classroom discourse analysis, which, drawing on critical ethnography as a research tool, has “a transformative function” and “seeks to play a reflective role, enabling practitioners to reflect on and cope with sociocultural and sociopolitical structures that directly or indirectly shape the character and content of classroom discourse” (Kumaravadivelu, 1999: 473).

The related domain of language testing has also taken a critical turn in recent years. In Spolsky’s history of the development of the TOEFL exam, it is clear from the outset that “testing has been exploited also as a method of control and power – as a way to select, to motivate, to punish.” So-called objective tests, he points out, by virtue of their claims to scientific backing and impartiality, are “even more brutally effective in exercising this authority” (Spolsky, 1995: 1). These concerns have been pursued furthest by Shohamy in her notion of critical language testing (CLT) which “implies the need to develop critical strategies to examine the uses and consequences of tests, to monitor their power, minimize their detrimental force, reveal the misuses, and empower the test takers” (Shohamy, 2001: 131). Shohamy’s proposal for critical language testing clearly matches many of the principles that define other areas of critical applied linguistics: her argument is that language testing is always political, that we need to become increasingly aware of the effects and uses of tests, and that we need to link preferred visions of society with an ethical demand for transformative practice in our own work as (critical) applied linguists. Doing applied linguistics critically, then, implies an interest in the workings of power, a concern with issues of inequitable access to and through domains of language, consideration of the effects of social and cultural difference, and attention to the ways in which people are located, understand themselves, and have opportunities to change.

The Critical in Applied Linguistics

The emergence of these various critical projects has been met with mixed responses. For some, critical

applied linguistics is little more than a critique of other orientations to applied linguistics; thus, Davies provides the following definition: “a judgmental approach by some applied linguists to ‘normal’ applied linguistics on the grounds that it is not concerned with the transformation of society” (Davies, 1999: 145). Yet it is clear from the previous section that critical applied linguistics is not so much a critique of ‘normal’ applied linguistics (though it certainly may engage in such critiques) but is rather a different, alternative, or even transgressive way of doing applied linguistics. A central concern in discussing critical applied linguistics, then, is what is actually meant by the term ‘critical.’ One position would argue that all good academic work is by nature critical, entailing an open mind, a degree of skepticism, and an ability to keep a form of academic distance from the objects of inquiry. From this point of view, it is crucial to avoid bringing one’s own judgments into any form of academic inquiry. Thus, Widdowson, for example, in arguing for a “critical, not a hypocritical, applied linguistics to take us into the future” (Widdowson, 2001: 16), is concerned that by taking an *a priori* critical stance, critical applied linguistics may impose its own views on the objects of inquiry, taking inappropriate stances on the social world rather than maintaining a critical distance. For Widdowson, it is impossible as an applied linguist (though not necessarily as an individual) to choose between different ethical and political concerns, and thus critical applied linguistics hypocritically fails to maintain a critical distance.

An alternative position, however, turns the tables on Widdowson’s dichotomy, suggesting that it is mainstream applied linguistics that is hypocritical by dint of its inability or unwillingness to grapple adequately with the social, political, and ethical concerns that inevitably come to bear on any applied linguistic context. By making claims to deal with real world issues to do with language, but by failing to engage with questions of power, inequality, racism, sexism, or homophobia in relation to discourse analysis, translation, language learning, literacy, or language in the workplace, mainstream applied linguistics might therefore be described as espousing a form of liberal ostrichism (Pennycook, 2001) in its relativistic refusal to engage with the social, political, ethical, and epistemological concerns of an inequitable world, and the tendency for applied linguists to bury their heads deep in the sand and eschew engagement with the broader context of applied linguistic work. This second sense of the critical, to which Widdowson objects, is one which draws on a long history of critical theory, and takes as its starting point the analysis of power and inequality in the social world.

From this point of view, academic responsibility requires more than critical distance; rather, it demands that we attempt to address social, cultural, and political concerns head on, with an explicit political agenda.

If a strong case can thus be made for the unavoidability of political engagement, the concern nevertheless remains that critical applied linguistic research may be blinkered by its political normativity. Indeed, it may be argued that much of critical applied linguistics operates with a normative, leftist political agenda and a conservative applied linguistic epistemology. That is to say, it follows a modernist emancipatory framework (Pennycook, 2001), bringing together a static politics based on various forms of neo-Marxian analyses of inequality and emancipation, with an equally static applied linguistic epistemology. In addition to a political focus on inequality, then, critical applied linguistics also needs a form of problematizing practice. From this point of view, critical applied linguistics is not only about relating micro-relations of applied linguistics to macro-relations of social and political power; nor is it only concerned with relating such questions to a prior critical analysis of inequality. A problematizing practice, by contrast, suggests a need to develop both a critical political stance and a critical epistemological stance, so that both inform each other, leaving neither the political nor the applied linguistic as static. From this point of view, then, critical applied linguistics maintains both a consistent focus on issues of dominion, disparity, difference, and desire while at the same time maintaining a constant skepticism toward cherished concepts such as language, grammar, power, man, woman, class, race, ethnicity, nation, identity, awareness, and emancipation. Remaining aware of the diverse contexts in which it may hope to be applicable, this transgressive applied linguistics remains wary lest the very terms and concepts of any critical project at the same time inflict damage on the communities it is aiming to assist. This form of critical applied linguistics is far more than the addition of a critical/political dimension to applied linguistics; rather it opens up a whole new array of questions and concerns about language, identity, sexuality, ethics, and difference.

Applied Linguistics and the Critical

Elder suggests that “the very existence of a transgressive critical applied linguistics which attacks the foundations and goals of applied linguistics is perhaps a sign that applied linguistics is a discipline which has come of age” (Elder, 2004: 430). The emergence of critical applied linguistics, however, has broader implications for applied linguistics than mere

maturity. By drawing on a far more extensive range of external domains than is often the case with applied linguistics, critical applied linguistics not only opens up the intellectual framework to many diverse influences, but also makes old debates over linguistics applied versus applied linguistics (for example, Widdowson, 2001) little more than a red herring. As Rajagopalan suggests, we may now start to view applied linguistics as a “*transdisciplinary* field of inquiry,” which means “traversing (and, if it comes to the push, *transgressing*) conventional disciplinary boundaries in order to develop a brand new research agenda which, while freely drawing on a wide variety of disciplines, would obstinately seek to remain subaltern to none” (Rajagopalan, 2004: 410). Thus, by taking not only a broad view on knowledge but also a political view on knowledge, critical applied linguistics transcends a conception of applied linguistics as a fixed discipline, or even of applied linguistics as a domain of interdisciplinary work, and opens the doors to a diversity of epistemological influences. While Davies may lament such a position as being “dismissive totally of the attempt since the 1950s to develop a coherent applied linguistics” (Davies, 1999: 141), critical applied linguistics will always be concerned about the interests behind such constructions of coherence.

Critical applied linguistics in fact plays a crucial role in opening the narrowly defined domains of a coherent applied linguistics to a range of different theoretical positions. It is responsive not so much to shifts in mainstream linguistic and applied linguistic theory, but rather to the linguistic, somatic, and performative turns elsewhere in the social sciences. To the extent that applied linguistics remains partially dependent on linguistics, it has been hampered by the inability of linguistics to deal with the linguistic turn in the social sciences. Thus applied linguistics has been desperately slow to address such concerns. It is only recently, as Canagarajah puts it, that we have started to “redefine our understanding of the human subject. We have borrowed constructs from disciplines as diverse as philosophy, rhetoric, literary criticism, and the social sciences. We have adopted different theoretical positions ranging across feminist scholarship, language socialization studies, Bakhtinian semiotics, and Foucauldian poststructuralism. These schools have helped us understand identities as multiple, conflictual, negotiated and evolving. We have traveled far from the traditional assumption in language studies that identities are static, unitary, discrete, and given” (Canagarajah, 2004: 117). Understandings of the role of discourse in constituting the subject, of the subject as multiple and conflictual, of the need for a reflexivity in knowledge

production, are slowly starting to emerge in applied linguistics, led by work in critical applied linguistics.

At the same time that the linguistic turn has swept across the social sciences, there has also been a somatic turn, a turn towards the body. For some, the somatic turn runs counter to the perceived logocentrism of the linguistic turn, though others suggest it is more of a redressing of this imbalance so that we can see that the social order is both textual and corporeal. For Bourdieu, the somatic turn has been part of an attempt to understand how dispositions are written onto our bodies, how cultural capital is not something we pull on and take off but is deeply bound up with how we act. "The sense of acceptability which orients linguistic practices is inscribed in the most deep-rooted of bodily dispositions; it is the whole body which responds by its posture, but also by its inner reactions or, more specifically, the articulatory ones, to the tension of the market. Language is a body technique, and specifically linguistic, especially phonetic, competence is a dimension of bodily hexis in which one's whole relation to the social world, and one's whole socially informed relation to the world, are expressed" (Bourdieu, 1991: 86). Applied linguistic orientations to the body have to date generally been limited to versions of nonverbal communication, but again, as critical applied linguistics opens up this orientation to understanding the relation between the social order, language, and the body, it is starting to push more mainstream work in new directions.

Finally, the growing interest in identity across other fields of inquiry is increasingly affecting (critical) applied linguistics (see, for example, Norton, 2000). At the forefront of this focus on identity is the performative turn, and the crucial insight that identities are **performed** rather than **preformed**. Central to this move toward the performative has been Butler's argument that "gender proves to be performative – that is, constituting the identity it is purported to be. In this sense, gender is always a doing, though not a doing by a subject who might be said to preexist the deed" (Butler, 1990: 25). These arguments have been most influential in queer studies, where the questioning of categories of sexual and gender identity has allowed a framing of sexuality that goes beyond lesbian and gay identification and instead embraces the broader category of queer (Nelson, 1999). Cameron points out that such a position has serious implications for sociolinguistics and studies of language and gender, since "sociolinguistics traditionally assumes that people talk the way they do because of who they (already) are," whereas a performative approach to identity "suggests that people are who they are because of

(among other things) the way they talk" (Cameron, 1997: 49). The question for language and gender studies (or any other focus on language and identity), then, is not how men and women talk differently, as if males and females preexisted their language use as given categories of identity, but rather how to do gender with words. This does not mean that we do not constantly perform gendered identities through language but rather that we constitute through language the identity it is purported to be. It is in the performance that we make the difference. Again, cutting edge work in critical applied linguistics is starting to open up applied linguistics to such perspectives.

This view suggests, then, that a transgressive, critical applied linguistics has become far more than a political add-on to mainstream applied linguistics. It has now, by contrast, become the gateway through which new theories and ways of thinking about applied linguistics are entering and changing the discipline. A newly emergent approach to critical applied linguistics has superseded the static politics and epistemologies of the modernist emancipatory framework, and started to take on board the implications of the linguistic, somatic, and performative turns, with major implications for applied linguistics more broadly. It accepts that we have to confront the crisis of realist representation in Western academic life and the need for reflexivity in knowledge production, that we need to understand the role of discourse in constituting the subject, and that the subject is multiple and conflictual. At the same time it acknowledges that the logocentric idealism of an overemphasis on discourse overlooks the ways in which the social order is not only about language, textuality, and semiosis but is also corporeal, spatial, temporal, institutional, conflictual, and marked by sexual, racial, and other differences. The somatic turn allows applied linguistics to readdress the embodiment of difference, while the performative turn suggests that identities are formed in the linguistic and embodied performance rather than pregiven. This in turn provides the ground for considering languages themselves from an antifoundationalist perspective, whereby language use is an act of identity that calls that language into being. These are the concerns of an exciting new era of transgressive applied linguistics.

Critical Discourse Analysis

T van Leeuwen, Cardiff University,
Cardiff, UK

Introduction

Critical discourse analysis is founded on the insight that text and talk play a key role in maintaining and legitimating inequality, injustice, and oppression in society. It employs discourse analysis to show how this is done, and it seeks to spread awareness of this aspect of language use in society, and to argue explicitly for change on the basis of its findings.

Critical discourse analysis is not associated with a specific school of linguistics or discourse analysis. Many have followed Fairclough (1989) in drawing primarily on the systemic-functional linguistics of Halliday (1989). According to Halliday, the resources of language simultaneously fulfill three major functions: the **ideational** function of constructing representations of the world; the **interpersonal** function of constituting social interactions; and the **textual** function of creating cohesively structured texts and communicative events. This suits the purposes of critical discourse analysis, which engages both with the way language is used to construct and disseminate discourses – ideologically specific representations of some aspect of the world – and with the way language is used to enact hegemonic genres – specific ways of using language to achieve purposes of social domination. Fairclough (1993: 134; 2000: 14, see also van Leeuwen, 2005) added styles – uses of language to construct and enact social identities.

But many critical discourse analysts use other methods, including, for instance, argumentation strategies (e.g., Wodak and Matouschek, 1993), narrative analysis (see e.g., Mumby, 1993), forms of conversation analysis that go beyond the constraints stipulated by proponents such as Schlegoff (1997) and link conversational data to their wider social context (e.g., Ehrlich, 1998), and more. While Fairclough and others (e.g., van Leeuwen, 1996) have adapted and elaborated systemic-functional linguistics for purposes of critical discourse analysis, van Dijk (e.g., 1993a) and others have demonstrated that a much wider range of methods can usefully be applied in critical discourse analysis, arguing for a multidisciplinary approach which “chooses and elaborates theories, methods and empirical work as a function of their relevance for the realization of socio-political goals” (1993a: 252). The methodological diversity of critical discourse analysis is well demonstrated in

the pages of *Discourse and Society*, which has been the key journal for critical discourse analysis over the past 17 years.

Critical discourse analysts engage not only with a range of discourse analytical paradigms, but also with critical social theory. In more recent work social theory may even dominate over discourse analysis. Fairclough in particular has consistently explored ways of grounding critical discourse analysis in critical social theory (see Chouliaraki and Fairclough, 1997). Strongly influenced by Marx and Gramsci, Fairclough's work also engages with Foucault, Bourdieu, Habermas, Harvey, and Giddens, to mention just a few names. But, again, there is no theoretical orthodoxy in critical discourse analysis. With regard to the key concept of **ideology**, for instance, van Dijk (1993a: 258; 1998), sees ‘ideologies’ as the ‘worldviews’ that constitute ‘social cognition’: “schematically organized complexes of representations and attitudes with regard to certain aspects of the social world, e.g., the schema (...) whites have about blacks, which may feature a category ‘appearance’,” while Fairclough has a more Marxist view of ideology in which ideologies are “constructions of practices from particular perspectives (...) which iron out the contradictions, dilemmas and antagonisms of practices in ways which accord with the interests and projects of domination” (Chouliaraki and Fairclough, 1997: 26). But this has not led to divisions within critical discourse analysis. What unites critical discourse analysis is neither methodology nor theoretical orthodoxy, but a common goal: the critique of the hegemonic discourses and genres that effect inequalities, injustices, and oppression in contemporary society.

The issues critical discourse analysts have explored over the past 20 years have also varied widely. A great deal of work, particularly by Wodak (e.g., Wodak *et al.*, 1990; Wodak and Matouschek, 1993) and van Dijk (e.g., 1991, 1993b) and their associates has focused on racism and antisemitism, and more recently also on immigration and asylum (e.g., Van Leeuwen and Wodak, 1999). The discourses of neoliberalism and their role in the neocapitalist policies and practices of governments, the business world, and other institutions have become another important focus (e.g., Fairclough, 1993, Chouliaraki and Fairclough, 1997, Fairclough, 2000). But the pages of *Discourse and Society* and collections such as Toolan (2002) show that critical discourse analysts have addressed many other issues as well, including gender, education, doctor-patient communication, war and terrorism, and welfare and unemployment, to mention

just a few. The data used by critical discourse analysts also vary. Although there has been a tendency to focus on speeches by politicians, parliamentary debates, and media reports and editorials, critical discourse analysts have also analyzed school textbooks, advertisements, the books of management gurus, transcripts of doctor-patient and workplace meeting interactions, and much more. And as a glance at the contents of *Discourse and Society* will demonstrate, this work has increasingly come from all corners of the world.

Critical Linguistics

The immediate forerunner of critical discourse analysis was critical linguistics, a movement that started at the University of East Anglia in the mid-1970s (Fowler *et al.*, 1979; Hodge and Kress, 1993). Halliday's systemic-functional linguistics provided the fundamental insight that made it possible to move linguistic analysis beyond formal description and use it as basis for social critique (1989: 101):

Grammar goes beyond formal rules of correctness. It is a means of representing patterns of experience (...) It enable human beings to build a mental picture of reality, to make sense of their experience of what goes on around them and inside them.

Critical linguists added two further steps. The first was inspired by Marx. The "patterns of experience" Halliday refers to, they argued, are not necessarily neutral. They are patterned the way they are to suit the needs and interests of those who use them both to understand and to enact their reality, and if such interests include domination, they are ideological. The second was inspired by Whorf. If different languages can encode different "patterns of experience" (and different ideologies), they argued, so can different uses of one and the same language. In a study that has rightly become a classic, Tony Trew (1979: 106–107) described how, when the Harare police, in what was in 1975 still Rhodesia, fired into a crowd of unarmed people and shot thirteen of them The *Rhodesia Herald* wrote: "A political clash has led to death and injury," while the *Tanzanian Daily News* wrote, "Rhodesia's white supremacist police (...) opened fire and killed thirteen unarmed Africans." Analyzing texts of this kind, Trew demonstrated that political views are not only encoded through different vocabularies (of the well-known freedom fighter versus terrorist type) but also through different grammatical structures, here for instance through the coding of the same event as either a noun ('death') or a verb ('kill') that, for its grammatical completion,

requires an active subject ('police') and an object ('Africans'), so that both the perpetrators and the victims must be referred to explicitly. Another key example of what critical linguists have called "ideological transformations" is passive agent deletion: if the Tanzanian version were to be passivized ("Thirteen unarmed Africans were killed...") it would no longer be necessary to name the police as the agent of the killing.

With work of this kind, critical linguists took the fundamental step of interpreting grammatical categories as potential traces of ideological mystification, and broke with a tradition in which different ways of saying the same thing were seen as mere stylistic variants, or as conventional and meaningless indicators of group membership categories such as class, professional role, and so on. Without their work, critical discourse analysis would not have been possible.

Critical Discourse Analysis

Critical discourse analysis started in the mid-1980s as a new direction in the work of Fairclough, van Dijk, Wodak, and others. As a movement it began in 1992, at a meeting in Amsterdam with presentations by van Dijk, Fairclough, Wodak, Kress, and van Leeuwen, which were later published as a special issue of *Discourse and Society* (4, 2, 1993). The group gradually expanded and continued to meet annually from 1992 onward. Another early collection of influential papers was published a few years later (Caldas-Coulthard and Coulthard, 1996). Since then critical discourse analysis, now usually referred to as CDA, has been a fast growing and increasingly interdisciplinary movement. A first large-scale international conference was held in 2004 in Valencia. Two new journals started in the same year, *Critical Discourse Studies* and the *Journal of Language and Politics*.

Critical discourse analysis moved beyond critical linguistics in a number of ways. The first has already been mentioned: the attempt to ground critical discourse analysis in critical social theory and to articulate the relation between discourses and the social practices in which they are embedded. By the early 1990s, discourse had also become a key term in post-modern philosophy and cultural studies, and critical discourse analysis explicitly distanced itself from the dominant tendency in these fields to reduce the social to discourse, and discourse only. Concepts such as marketization (Fairclough, 1993) could incorporate both changing practices (the market practices that are now introduced in many institutions, including

universities) and the changing discourses that played a key role in this process by proposing and legitimating changes, training people in new practices, requiring them to learn new ways of talking and writing, and so on. As universities had to learn to compete with each other for students, treat students as customers, and so on, their discourses were also marketized. Job advertisements, for instance, changed from traditional forms such as “Applications are invited for a lectureship in the Department of English Literature ...” to forms such as “The Department of Law is a thriving department committed to excellence in teaching and research ...,” to accommodate the new emphasis on and entrepreneurial ethos and self promotion. Fairclough stressed the interdiscursivity of such genres. The old continues alongside the new, certainly for as long as the new practices still cause tension and have not stabilized.

Critical discourse analysis also moved beyond critical linguistics in adopting a much more fully interdisciplinary approach, studying not only texts and transcripts of talk, but also their contexts, whether by historical or ethnographic methods. Wodak’s ‘discourse-historical approach’ set the example here, increasingly involving collaborations between discourse analysts, on the one hand, and historians, political scientists, anthropologists, and sociologists on the other hand, as well as stimulating reflection on interdisciplinarity itself (e.g., Weiss and Wodak, 2003).

Critical discourse analysis has also moved beyond language, taking on board that discourses are often multimodally realized, not only through text and talk, but also through other modes of communication such as images. Kress and van Leeuwen (1996) developed methods of visual analysis that were strongly inspired by Halliday’s systemic-functional linguistics and demonstrated how these methods could be used for purposes of critical discourse analysis. To mention an example, van Leeuwen (2000) shows how ‘visual racism’ is realized not just by the most obvious racist stereotypes, but also through subtler methods. The members of some social groups, for instance, are never personalized, never depicted as individuals with unique characteristics. They are represented *en groupe*, often in highly similar or identical poses. This can then create a ‘they are all the same’ or ‘you can’t tell them apart’ effect. Again, the members of some social groups are consistently depicted in ‘long shot’, which, literally and figuratively, ‘distances’ them from the viewer.

Overall, then, critical discourse analysis has moved towards more explicit dialogue between social theory and practice, richer contextualization, greater interdisciplinarity and greater attention to the multimodality of discourse.

Critiques

Critical discourse analysis is no longer of interest only to linguists. The work published in journals such as *Critical Discourse Studies* and the *Journal of Language and Politics* shows that social scientists from a range of different fields are actively engaging with critical discourse analysis. By contrast, CDA has received some strong-worded critiques from within linguistics. These have often been included in collections of CDA papers (e.g., Toolan, 2002) and in the prescribed reading lists of university courses in linguistics departments, thus encouraging a certain suspicion of critical discourse analysis, especially in contexts where linguistics is taught and practiced as a neutral scientific enterprise.

In one of the most widely quoted critiques, Widdowson (1995, 1996) argues that it is the business of discourse analysis to describe formal patterns ‘above the sentence’ and that critical discourse analysts confuse discourse analysis with textual interpretation. In a similar vein Stubbs (1997) calls the analyses of critical discourse analysts ‘textual commentaries.’ Like Widdowson, Stubbs mainly targets Fairclough, conveniently ignoring the wide range of critical discourse work published over the years in *Discourse and Society* and elsewhere. The text analysed in Fairclough (1989), which are often pedagogical examples to demonstrate methods of analysis in what is essentially a textbook, are, according to Stubbs, “fragmentary” and “insufficient” because they do not constitute a representative sample and do not involve the kind of large scale quantitative work in which many linguists are now engaged.

Most of all, however, these critiques take offense at the explicit social and political goals of critical discourse analysis. Widdowson, for instance, argues that texts are differently interpreted by different readers and that critical discourse analysts unfairly privilege their own interpretations. From the point of view of critical discourse analysis (see e.g., Fairclough, 1996), traditional sociolinguistic and stylistic approaches to the study of language in social life may have succeeded in describing patterns of language use and patterns of language change, but they have not explained them. They have treated them as more or less meaningless conventions and autonomous evolutionary processes. Critical discourse analysts are seeking to explain why texts are the way they are, and why they change the way they do, and following Halliday, they look for the answers to these questions in the social, economical, and political world.

Critical discourse analysts are aware that their own work, too, is driven by social, economical, and political motives, but they argue that this applies to all

academic work. Social divisions of labor have traditionally ensured that scientists and other academics do not have to confront the conditions that make the continuation of their work possible and the place it has in the wider scheme of things. Critical discourse analysts at least make their position explicit and feel they do not need to apologize for the critical stance of their work; on the contrary, by contributing to debates on issues that are of crucial importance to society, they continue the tradition of reasoned debate that has been fundamental to democratic societies since antiquity, feeling that their work as scholars entails greater social responsibilities than providing facts for others to interpret and use.

Cultural and Social Dimension of Spoken Discourse

J B Haviland, Reed College, Portland, OR, USA

© 2006 Elsevier Ltd. All rights reserved.

'Spoken discourse' is a fancy name for the sort of language we live with in the course of ordinary life, the source from which we all acquire not only language itself but, indeed, major aspects of our social and cultural worlds. It is largely through spoken interaction with others that we learn not only what sorts of social identities there are, and how to recognize them, but in fact how to construct and present ourselves as persons. Insofar as most meaningful social action is accomplished in large part discursively, it is also through speech that we carry out much of the business of our lives.

Within linguistics, the study of discourse is frequently distinguished from other structural inquiries simply by the size and scope of the units of analysis. When one looks at linguistic entities larger than sentences, takes into consideration the organization of textual fragments, or begins to encompass turns at talk across different speakers, tools that were useful in analyzing sounds, words and their parts, or clauses become insufficient. It is in the choice of larger bodies of language, too, that the communicative traditions of specific social and cultural communities become immediately and unavoidably relevant. For what warrants selecting some particular fragment of speech as a unit in the first place? What gives it coherence and separates it from other surrounding talk?

Cultural considerations are always at work in such judgments. What makes a stretch of talk into a complete 'conversation' or 'mathematics lesson' or 'curing ceremony' or 'farewell'? Local criteria for what constitutes 'talk' in the first place can vary widely. From the beginning of anthropological attention to speech, theorists have grappled with differing notions of what is *real* talk – often highly specialized genres like prayer ('talk with God'), or denunciation and declamation in ritual or highly public settings – versus what is simply 'small talk' (gossip, a casual conversation, a greeting on the path), or not even 'talk' at all (perhaps a gesture, the babbling of an infant, the calls of animals, or the voice of the wind – for some communities real communication, if by nonhuman interactants, whereas for others even true discourse with intentional, albeit not volitional, participants).

Equally variable, then, are the sorts of participants spoken discourse admits. Discourse requires interlocutors, and these come in different flavors, not all equally endowed with voices or privileges to use them.

(In some communicative traditions, 'children are to be seen and not heard'; in others, wisdom comes 'out of the mouths of babes.') Different genders, castes, classes, ages, and ethnic identities may be differentially voiced or devoiced, and the resulting discourses will be differentially marked by what have been called 'participation frames': matrices of interlocutors, with different sorts of rights and obligations for speaking, differential access to the speech of others, and different sorts of statuses – whether recognized, ratified, authoritative, or the reverse – and stances (authoritative, indifferent, oppositional, etc.) in relation to the resulting talk.

The provenance of every piece of discourse is thus some social occasion for talk, and the textual sediment of the discourse will therefore always carry traces of its sociocultural (and political and historical) origins: why people had the linguistic interchange, and what happened (to them, between them, for them) when they did. An incidental but important consequence for research on spoken discourse is thus ethical: the identities and purposes of interlocutors may require careful treatment in any empirical description or analysis, since unlike canonical sentences, rarely are discursive fragments generated in the (relatively) neutral social and political climate of elicitation or introspection.

The social character of spoken discourse is also clear in the texture of speech itself. (Aspects of the spoken medium, incidentally, have analogues in other linguistic modalities, such as sign, a topic beyond the scope of this article.) By definition we think of the medium as verbalization – spoken words – but other sorts of signals are routinely involved. Spoken discourse routinely includes vocal sounds other than phonation, voice qualities, nonspeech vocalizations (e.g., sighs, laughs, grunts), and other noises, which may have local and partly conventionalized import (a finger snap, a clap, a stomp, a slap, even a slammed door, a tapping pencil, or a spoon on a glass). Moreover, gestures and in general motions and attitudes of the body – themselves subject to cultural shaping (think of a nod, a bow, a wink, or a shrug) and to ideological shading ('it's not polite to point') – may form a central part of interaction, coordinating the discourse itself or complementing other signaling modalities. The popular idea that one can tell where people are from or who they are by watching them interact – whether true or not – confirms how folk linguistics understands that discursive *styles* are cultural products.

Discourse is intrinsically four-dimensional, unfolding in both space and time in a way that defies

the often linear idealizations of linguistic analysis at the clause level. Discourse is also typically both polyphonic and polyvocal, combining multiple voices sometimes simultaneously and sometimes in orchestrated and partially overlapping sequences. Both aspects of spoken discourse are complicated by the sociocultural matrix in which it is produced.

Because it always unfolds in space and typically involves multiple participants, discourse can be structured in part by how interactants are arranged: how they stand or sit with respect to one another, how they are distributed in the physical environment, how they orient themselves to one another, and what sort of access (visual and aural, if not tactile and olfactory as well) they have both to other interactants and to other entities in the surrounding environment. Cultural structuring of space is thus the fundamental grounding of the resulting talk.

More insistent still is temporal structure in discourse, which always emerges as sequences of smaller linguistic units. When there are multiple interlocutors, units can overlap, be truncated, or abort prematurely. Sequences can stop and restart or can embed themselves within one another. There can be gaps, long or short. Generally time is the platform for speech, so that interlocutors can play with rhythm, synchrony, and asynchrony. Differences in temporal styles, then, can also emerge, distinguishing cultures, event or activity types, and individuals, often with value judgments and cultural stereotypes attached ('fast talkers' do not simply talk fast).

The four-dimensionality of spoken discourse merges most directly with its sociocultural underpinnings in the turn-taking system. Because there can be competition for discursive resources – the 'floor' (or its avoidance, through reticence or silence); the topic, the story line, or the punch line; authority and responsibility (and their ducking or shirking) – speaking is always a matter of politics, though the power involved may be microscopic and subtle. Who gets turns, who takes turns, and who is denied turns – and how these turns are shaped – are thus always matters of social import. Society also defines who (and what) can be addressed, who can hear, and who must not. Accordingly, there are miniature social and political structures implicit in different systems of turn allocation (contrast a courtroom or a barroom with a classroom or a locker room).

Structures of participation in spoken discourse have a further sociopolitical dimension, in that interlocutors never interact in a biographical vacuum. Their identities and personal histories, to a greater or lesser extent, public and shared between interactants, shape their talk as well as talk directed to them or around them. Some discourse theory concentrates on

the mutual building of 'common ground,' or shared knowledge, between interactants in talk, but discourse begins with most shared belief already in place, legislated by prior experience (centrally including prior discourse). The sometimes covert sociopolitical structure also gives rise to 'recipient design': the fact, noted long ago by Bakhtin, that discursive 'moves' – turns at talk – are specifically tailored, in the moment, both to the purposes at hand and to the specific social personae present. Not only 'semantic' content but everything from syntax and lexicon to accent and eye gaze is part of the 'design' of talk in relation to its socially constituted targets.

There are processing consequences of the sociocultural embedding of discourse, also a product of temporality overlain by participation structures. For some theorists (Clark (1996), for example), the hallmark of talk is that it is a prototypical joint and collaborative activity that requires coordination of various kinds between interlocutors. It cannot be done alone, and to talk at all requires participants to find ways to coordinate, often without knowing exactly what is going to happen next. Both cognitive skills – the ability to infer meaning and intention, for example – and cultural routines (various 'scripts' that allow cultural experts to anticipate what will or should come next) may be involved in producing such coordination. Nonetheless, a hallmark of spoken discourse is that it is ordinarily neither preplanned nor (except in limited ways) editable, and thus it requires interlocutors to stay on their communicative toes. It is perhaps the extemporaneous quality of much spoken discourse that makes it, in Bakhtin's (1986) terms, a primary genre, a source of raw material that other sorts of language draw upon.

Spoken discourse is usually also employed for other cultural purposes: it is part of activity. Since multiple things can be happening within a single turn (Goodwin, 1981), 'parsing' discourse is not strictly a structural matter but rather requires both interlocutors and analysts to calibrate a wider context of activity and participation with the specific internal dynamics of an utterance. Such parsing is 'online' – immediate to the context and concurrent with anything else that may be going on – so that the indexical links between whatever is happening and forms of talk (the ways that speech indicates what is happening and that action partly determines the accompanying talk) are constantly in a process of revision and update. Discursive interlocutors can start off 'doing' one thing and end up accomplishing another, with multiple other 'speech acts' flitting in between.

The fact that spoken discourse ordinarily takes place 'face-to-face' also has social consequences.

Some of these stem simply from the physical presence of interactants, equipped with all their bodily trappings and sensibilities. For example, physical co-presence means that corporal expressions of a cultural milieu are immediately available for discursive exploitation and incorporation. Smell and touch can be invoked as much as sound or sight, and the orientation and disposition of bodies in interaction is usually significant for discourse, signaling aspects of participation (or exclusion) and commitment to the discursive task at hand, and is sometimes itself socially regimented (the seating arrangements at a *fono*, or a dinner table). Copresence means, too, that the *absence* or withholding of explicit signals may also be communicative; silence may do social work within conversation, as can avoidance of eye contact and physical distance and withdrawal.

Similarly, speech occurs in a wider physical environment, mapped and rendered significant by cultural treatment. (Recall Goffman's (1981) example of the outrageous hat that served as direct referent to the anaphoric 'it' in 'I don't like it.')

Not only may physical objects have cultural significance for discourse to feed on (the colored and significantly textured patches of ground in an archeology dig, for example), but so may the environment be populated with otherwise invisible 'cultural entities' (the space where a historical figure's house once stood, for example, serving as an invisible mnemonic sign for the person himself).

Finally, consider the cultural wrappings around both the digital and analogue signaling channels in spoken discourse. Words and morphemes in the stream of speech are of course subject to the familiar sociocultural and historical fashioning that produces any linguistic code. Additionally, culturally specific emblems – gestural holophrases – conventionally complement or substitute for speech, and these clearly differ from one speech tradition to the next. (Think of the different significance across the world of gestures with different raised fingers, for example.) Conventions of form as well as meaning apply (a 'thumbs up' gesture is not the same with any other finger or with the thumb placed slightly at an angle). Beyond the hands, there are nods, shrugs, and a variety of other conventionalized bodily signs that punctuate and modulate the ordinary linguistic channel.

However, many analogue signaling devices characterize spoken discourse, and these, too, may be subject to cultural shaping.

Discourse depends – minimally for successful reference – on indexical links between discursive elements and contextual entities. *Pointing* is a device for indexically picking out a referent in the neighborhood (variously scaled and constructed) of

interlocutors, and similar semiotic processes are involved in what Clark (2003) called *placing* – manipulating or moving entities in the environment as a way of incorporating something into discourse. Cultural convention often conditions how one is to point; e.g., in many Australian languages (and probably elsewhere), referents – even imaginary ones – are carefully located in space with respect to cardinal directions or other cultural standards. Analogue indexical devices are also typically ideologically charged. There may be socially polite and impolite ways to point or to handle things – for example, to pass them from one person to another. Speech that involves such gestures inherits properties from its component communicative acts. It also draws upon cultural conventions when, for example, the formation of 'iconic' gestures draws on local standards of 'similarity.'

A further analogue signaling device prominent in spoken discourse is gaze. Where interlocutors look can show both a speaker's bid for an addressee's attention and the other's acquiescence, although here, too, cultural factors may alter both expectations (as when people 'avert their eyes' or 'cannot meet your gaze'). Gaze can also be used to signal withdrawn or withheld attention. There are often accompanying ideologies (the admonition 'Don't stare!' or the detective's assessment of a 'shifty look.')

Facial expression more generally modulates the effects of speech: imagine an ironic smile accompanying rebuke or insult, or an angry look on top of an overpolite request. In sign languages, indeed, the face is one of the major 'phonological' articulators. In the verbal medium, of course, the most obvious counterpart is the voice, the final analogue signaling device to be mentioned.

Some speech communities conventionalize affect and emotion with ways of using the voice, and local theory may speak informally of, say, an 'angry voice' or relate a certain named voice quality ('whispered' or 'hoarse') to a particular communicative intent or to certain sorts of social identities ('falsetto' voice among Maya women, or 'question intonation' as a gender stereotype). The existence of such distinguishable speech symptoms also makes possible deliberate imitation or representation. 'Voicing' a protagonist by using his or her words and also his or her voice or bodily attitudes is the stock-in-trade of discursive virtuosi, among the most characteristic and versatile of cultural experts.

Default Semantics

K Jaszczolt, University of Cambridge, Cambridge, UK

© 2006 Elsevier Ltd. All rights reserved.

It is hardly contestable that the interpretation of the speaker's utterance by the addressee is frequently driven by the salience of some of the possible interpretations. This salience can be caused by a greater frequency of a certain meaning or by its simplicity, but ultimately it rests on knowledge of social and cultural conventions or the cognitive principles that govern our thinking. Default Semantics concerns such cognitive defaults.

Before laying out the principles of Default Semantics, it is necessary to situate the default-based views in the research on the semantics/pragmatics interface. According to the traditional view, in addition to lexical and syntactic ambiguities, there are also semantic ambiguities such as that between the wide and narrow scope of negation in (1), represented in (1a) and (1b) respectively. 'KoF' stands for 'present king of France'.

- (1) The present king of France is not bald.
- (1a) $\neg \exists x (\text{KoF}(x) \ \& \ \forall y (\text{KoF}(y) \supset y = x) \ \& \ \text{Bald}(x))$
- (1b) $\exists x (\text{KoF}(x) \ \& \ \forall y (\text{KoF}(y) \supset y = x) \ \& \ \neg \text{Bald}(x))$

The ambiguity position, held by Russell, among others, has been successfully refuted. Instead, it has been proposed that such differences in meaning belong to what is implicated rather than what is said (Grice, 1975) (*see Grice, Herbert Paul*), and subsequently that semantics can be underspecified as to some aspects of meaning and require pragmatic intrusion in order to arrive at the full propositional representation of the utterance (*see, e.g., Carston, 1988, 2002*) (*see Pragmatics and Semantics*). It is now usual to talk about the *underdetermination* of sense and *underspecification* of the logical form. According to some post-Griceans, such differences in meaning can be explained through default interpretations. The level of defaults has been conceived of in a variety of ways: as belonging (i) to semantics (as in Discourse Representation Theory, Kamp and Reyle, 1993, and

its offshoots, such as Segmented Discourse Representation Theory, Asher and Lascarides, 2003) (ii) to pragmatics (Bach, 1994); or (iii) to fully fledged social and cultural conventions, called presumptive meanings or generalized conversational implicatures (Levinson, 2000). All of these default-based approaches advocate some degree of semantic underdetermination, understood as conceptual gaps in the output of lexicon and grammar. In other words, the logical form, which is the output of the grammatical processing of a sentence, does not provide the totality of meaning of the proposition expressed by the speaker.

While this statement is certainly true, and while it also seems to be true that some pragmatic contribution is often required in order to get the correct truth conditions of the utterance, it does not mean that such an underspecified or underdetermined representation need be distinguished as an epistemologically real level in utterance processing. In Default Semantics, there is no semantic ambiguity, but there is no underspecification either. The logical form as the output of syntactic processing interacts with the information coming from the property of mental states of *having an object, being about* something, called their *intentionality*. So, if we ask where meaning comes from, we can point to two sources of meaning: (i) compositionality of the sentence meaning and (ii) intentionality of the mental state that underlies the sentence. Both are equally basic and equally important, and hence it would be incorrect to consider any information coming from intentionality as an additional, pragmatic level of utterance processing. They both belong to semantics. In dynamic approaches to meaning, such as Discourse Representation Theory, such a level of representation, called in Default Semantics an *intentionality-compositionality merger*, has been successfully implemented and seems to be more in the spirit of dynamic meaning than postulating any unnecessary underspecifications or ambiguities (*see Jaszczolt, 1999a, 1999b, 2000*).

Default Semantics is governed by three main principles: the Parsimony of Levels (PoL), Degrees of Intentions (DI), and the Primary Intention (PI):

PoL: Levels of senses are not to be multiplied beyond necessity.

DI: Intentions in communication come in various degrees: they can be stronger or weaker.

PI: The primary role of intention in communication is to secure the referent of the speaker's utterance.

In PoL, the principle of parsimony with respect to the proposed levels of meaning is taken further than in other post-Gricean approaches. Instead of discerning an underspecified logical form and pragmatic intrusion, both sources of meaning are treated on an equal footing and both contribute to a common level of representation (the intentionality-compositionality merger). DI and PI principles specify how intentionality contributes to the meaning representation. In agreement with the phenomenological tradition (Husserl, 1900–1901), we have defined intentionality as the property of beliefs, thoughts, doubts, etc., of being about an object. It is compatible with the definition of intentionality that this aboutness can be stronger or weaker. For example, a definite description ‘the best Italian painter’ can correspond to a thought about a particular individual, e.g., Michelangelo (and be used *referentially*); to a thought about a particular individual who does not correctly match the description, e.g., Picasso (i.e., there is a referential mistake); or finally to a thought about whoever happens to undergo the description (and be used *descriptively*). In the first case, intentionality is in the strongest form: as a property of the mental state, it reaches, so to speak, a real object. In the middle case, it is weaker: a real object is intended, but there is no such object corresponding to that description, and hence it reaches a mental construct that is a composite of the real person and an incorrect description. In the final case, the intentionality is dispersed and does not reach an object.

Now, intentional mental states need vehicles of meaning, and language is one such vehicle. As a result, linguistic expressions share the property of intentionality, and hence we can talk about intentionality of utterances as well as intentionality of thoughts. On the level of utterances, this intending is realized as *intentions in communication*. Three types of such intentions are distinguished in Default Semantics: an intention to communicate certain content, to inform about certain content, and to refer to objects, states, events, and processes. In accordance with the DI and PI principles, information from the degree of intentionality of the mental state (or the strength of intending, informativeness of

an utterance) merges with the information from compositionality and produces the complete propositional representation that conforms to PoL. So, Default Semantics offers a more economical alternative to the approaches founded on underspecified semantics in that it implements Occam's razor (the methodological principle of not multiplying beings beyond necessity) ‘one level up.’ Semantic representation structures of Discourse Representation Theory have been implemented as formalizations for such intentionality-compositionality mergers (Jaszczolt, 1999b, 2000, 2006).

The DI and PI principles, in recognizing degrees and strengths of intentions, explain how default interpretations can arise. In the case of definite descriptions such as ‘the best Italian painter,’ the hearer normally assumes that the speaker utters the description with a referential intention and that the description is used correctly. This assumption is further corroborated by the assumed intentionality of the speaker's belief: the intentionality is strongest when a particular, identifiable individual has been intended. By force of the properties of vehicles of thought discussed in this article, the stronger the intentionality, the stronger the speaker's intentions. In the case of definite descriptions, the stronger the intentionality, the stronger the referential intention. In the case of definite descriptions, there are three degrees of intentionality corresponding to the three readings distinguished previously: (i) the strongest, referential; (ii) the intermediate, referential with a referential mistake; and (iii) the weakest, attributive. The strongest intentionality corresponds to the default reading. This default reading arises instantly, as a compositionality-intentionality merger. Only if addressees have evidence from their knowledge base or from the context that this default is not the case does the default interpretation *fail to arise*. This procedure is an improvement on other default-based approaches where defaults have to be *canceled* or *overridden*. Cancellation of defaults is a costly process and should not be postulated lightly: if there is no evidence of such cancellation, it is better to do without it and assume a more economical model of utterance processing.

Similarly, cognitive defaults can be discerned for belief and other propositional attitude reports. Sentence (2a) can give rise to a report, as in (2b).

(2a) The best Italian painter painted this picture.

(2b) Mary believes that the best Italian painter painted this picture.

Using the representation of the Discourse Representation Theory (Kamp and Reyle, 1993; Reyle, 1993),

Figure 1 A combined DRS for the three readings of (2b).

we can represent the possible readings of (2) as in **Figure 1** (Jaszczolt, 1999b: 287):

The discourse referent *y* is enclosed by a box drawn with a broken line, which signals that *y* can belong to any of the three remaining boxes. If it belongs to the outermost box, the reading is *de re* (about a particular individual, say, Michelangelo). Placed in the middle box, it signals that Mary has a *de re* belief but is referentially mistaken, thinking, for example, of Picasso. Placing *y* in the innermost box corresponds to a belief about whoever undergoes the description, i.e., a belief in a proposition (*de dicto*) rather than about a particular individual. Analogously to the case of definite descriptions where referential use was the default, the *de re* reading of a belief report comes out as a default, because it corresponds to the strongest intentions and the strongest intentionality. So, **Figure 1** comprises three possible representations (three possible compositionality-intentionality mergers).

In addition to definite descriptions in extensional and in propositional attitude contexts, the mechanism of the principles of Default Semantics has been applied to a variety of language expressions and constructions, including proper names (Jaszczolt, 1999b), presuppositional expressions (Jaszczolt, 2002a, 2002b), expressions of temporality and modality, and tentatively to numerals and sentential connectives (Jaszczolt, 2005a, 2005b). Naturally, the PI principle will not always be relevant. The referential intention will not always be present, and even when it is, it may not pertain to the assessment of the default or nondefault status of various readings. For example, in an assessment of the default meaning of *will* from among the epistemic necessity *will* in (3), dispositional necessity *will* in (4), and a marker of future tense in (5), it is the intention to inform the addressee about a certain content that is graded from the strongest to the weakest:

- (3) Mary will be in the opera now.
- (4) Mary will sometimes go to the opera in her tracksuit.
- (5) Mary will go to the opera tomorrow night.

The Default-Semantic account of *will* also demonstrates that modal and temporal senses of *will* are traceable to one, overarching modal concept (akin to the sentential operator of *acceptability* in Grice, 2001). And since *will* is modal, it follows that the assignment of defaults has to be reversed as compared with the examples previously discussed: the weakest intentionality corresponds to the default sense of *will*, and this, predictably, turns out to be the regular future marker in (5) (for a formal account, see Jaszczolt, 2006).

Not all default interpretations are reducible to cognitive defaults. For example, the interpretation of possessives, as in (6), is dependent on the addressee's background knowledge and the context, rather than on the properties of mental states.

- (6) Peter's book is about a glass church.

Similarly, inferences to a stereotype ('female nurse'), such as in (7), are not the case of the strength of intending but rather stem from the acquaintance with social and cultural practices.

- (7) They employed a nurse to look after the patient.

Such default interpretations belong to the category of social and cultural defaults and are not always of central interest to semantic theory.

The phenomenon of negative-raising, i.e., the tendency for negation on the main clause to be interpreted as negation on the subordinate clause, is not an obvious cognitive default, but here we must be cautious. Neg-raising unpredictably applies to some relevant verbs but not to others, as (8) and (9) demonstrate.

- (8) I don't think he is dishonest. (communicates, defeasibly: 'I think he is not dishonest.')
- (9) I don't hope he will win. (does not communicate: 'I hope he will not win.')

The important question at this point is to ask about the scope of applicability of the theory. The question of the scope of applicability can be taken in the narrow and in the wide sense. In the narrow sense, we ask which default interpretations can be regarded as cognitive defaults, traceable to the properties of mental states. Cognitive defaults are rather widespread. In addition to the examples already mentioned, numerals seem to default to the 'exactly' meaning, rather

than being underdetermined between ‘at least,’ ‘at most,’ and ‘exactly,’ or having an ‘at least’ semantics. The enrichment of some sentential connectives such as *if* (to ‘if and only if’) and *or* (to exclusive *or*) can possibly also be traced to the strength of the informative intention and intentionality. This proposal concerning connectives and numerals is still highly programmatic and in need of further research. It is signaled here in order to shed some light on possible applications of cognitive defaults. In the wide sense, Default Semantics also comprises social and cultural defaults simply by assigning them an epistemological status that has nothing to do with the compositionality-intentionality merger.

To sum up: Default Semantics postulates a level of utterance interpretation called a compositionality-intentionality merger and thereby significantly decreases the role of underspecification in semantic theory. It distinguishes cognitive defaults and intention-based degrees of departures from these defaults, triggered by the addressee’s knowledge base and the context. The theory also acknowledges the existence of social and cultural defaults whose source lies beyond semantics proper.

Deixis and Anaphora: Pragmatic Approaches

K Green, Sheffield Hallam University, Sheffield, UK

© 2006 Elsevier Ltd. All rights reserved.

‘Deixis’ is generally understood to be the encoding of the spatiotemporal context and subjective experience of the encoder in an utterance. Terms such as *I*, *here*,

now, and *this* – the so-called ‘pure deictic terms’ – are heavily context dependent and represent a kind of cognitive center of orientation for the speaker. What, for instance is *here* for me, may be *there* for you. Clearly such terms pose problems in terms of both reference and meaning, and standard accounts have attempted to find a middle ground between

lexical and pragmatic meaning (see Green, 1995). The difference between ‘anaphora’ and deixis is fairly straightforward again in standard accounts (see Jarvella and Klein, 1982), but an increasing pragmatic emphasis has made the distinction between the two less easy to define. In standard accounts, anaphora is seen as much more of an intralinguistic or intrasentential element. Consider the following sentences:

That man is very tall. He must have trouble buying clothes.

The deictic expression *that man* must be given a pragmatic interpretation, while the pronoun *he* is said to ‘refer back’ to the foregoing element. But as we shall see, the issue is not so simple.

Anaphora is generally understood to be the process whereby a linguistic element is interpreted derivatively from a foregoing unit – its ‘antecedent.’ Although it covers a range of expressions that the speaker may use in referring and picking out the intended referent, research has focused almost exclusively on pronominal referring expressions in discourse, for example:

Fred came into the room. He sat down.

The theory of anaphora deals with the relationship between *he*, *Fred*, and the objects that these elements describe or pick out. The most problematic and interesting of anaphoric phenomena are those that are crosssentential or discourse based. In the taxonomy of Hankamer and Sag (1977), the antecedent is not considered to be crucial, and where it is not explicitly stated, the process is known as ‘pragmatically controlled anaphora.’ However, this is not central to the kind of pragmatic approaches that have recently been explored and indeed is close to what Halliday and Hasan (1986) and Brown and Yule (1983) would call ‘exophoric’ reference.

Pragmatic approaches to anaphora are part of a larger set of (sometimes conflicting) theories that Breheny (2002) calls ‘nondynamic.’ Within these non-dynamic approaches there are two subsections: ‘linguistic’ and ‘pragmatic’ approaches, the latter including what has come to be known as (following Cooper, 1979) ‘E-type approaches’. A nondynamic linguistic approach to the above example would stipulate that the pronoun in the second sentence is bound to the noun phrase in the first. However, one can still promote a ‘linguistic’ approach without the idea of crosssentential binding. In this approach, the pronoun serves as a proxy for a definite description and would therefore easily be accommodated within Hankamer and Sag’s model. The relationship between antecedent and pronoun is not so much syntactic as paradigmatic; the pronoun deputizes for the noun phrase. Linguistic approaches nevertheless

agree that some linguistic rule enables the description to be recovered, whether due to semantic or syntactic considerations (Heim, 1990; Neale, 1990) (see **Semantics-Pragmatics Boundary**).

Pragmatic approaches stress the absence of any generalized linguistic rule that would account for the recovery and interpretation of descriptions in anaphoric contexts. Rather, any principles about the process of recovery must be inferred from more general principles about discourse organization and context (see **Principles and Rules**). Consider the following example from Breheny (2002):

A man who walked in the park whistled.

Putting aside for the moment whether this is an appropriate sentence for analysis (that is, whether it is pragmatically plausible), two problems are evident here. The first is the problem of uniqueness, a particular difficulty when the antecedent is an indefinite (*a man*). In the model of Evans (1977) there must necessarily be only one man walking in the park; in other words, *a man* cannot be a disguised plural, giving rise to an ‘attributive’ (after Donnellan, 1978) reading of the phrase *a man who*. What linguistic rule tells us that this is so? The past tense of the verb *whistled* leads us away from any notions of generality as they tend to occur in timeless present contexts (*A man walking in the park whistles*). However, this by no means counts as a linguistic rule and is more readily interpreted through pragmatic means.

Another problem arises with contradictions. Again, consider the following from Breheny (2002):

A: Last night I met a Cabinet minister.

B: She was not a Cabinet minister.

Here, B does not ascribe to the description the property that A thinks it has. The pragmatic approach would have to rely on the notion of ‘implicit content’ to interpret this exchange. The proposition expressed by A cannot depend on the actual state of the referent. Clearly, pragmatic approaches can neatly sidestep both the uniqueness and contradiction problems, but they do so at a cost. The way the utterances are interpreted does not seem to rely upon any generalized notions of either discourse organization or contextualization. Rather, there is at most a general assumption about implicit communication, and we have no way of predicting which interpretation is correct or at least the most salient. As Breheny notes, this has led many to look further for some kind of **linguistic** rule; but there is no reason to suppose that because pragmatic rules are difficult to locate there must be a more formal linguistic answer (see **Constraint, Pragmatic**).

Where a pronoun is apparently bound to an indefinite expression without restriction, certain difficulties

arise, as in the following example (the so-called ‘donkey anaphora’):

Every farmer who owns a donkey beats it.

The problem for nonpragmatic accounts of anaphora here is that the indefinite (with its *wh*-clause) bound to the pronoun (*every farmer who owns a donkey*) is a quantificational noun phrase that actually has the pronoun in its scope.

Pronouns with definites as antecedents would appear to offer less of a challenge to pragmatic approaches, as in the earlier-cited example of *Fred came into the room. He sat down*. The traditional approach is to regard the pronoun as ‘coreferring’ to the name *Fred*, thus tying the pronoun variable to the noun phrase constant. But this makes the pronominal reference purely intralinguistic (as an element of ‘cohesion’) and wholly dependent upon its antecedent. A more pragmatic approach would be to see the pronoun as referring in a different way to that which *Fred* refers to. Just how different and in what way is difficult to specify, but certainly this approach makes pronominal reference of this kind very similar to deictic or exophoric reference; the line between deixis and anaphora is blurred. A problem with the traditional approach, which we might call the ‘binding’ or ‘cohesive’ approach, is that in indefinite contexts, what appears to be a straightforward binding of a quantificational expression and a variable (pronoun) does not represent a rule that can be generalized to a meaningful degree. In crosssentential examples such as *I had ten marbles but dropped them. I found nine. It had rolled under the sofa*, because the pronoun is not properly bound to its antecedent, there is no plausible interpretation. However, in the following example from Breheny, *Every boy left school early. He went to the beach*, the pronoun seems to convert the universal quantifier into an existential one.

There is a considerable body of work devoted to promoting pragmatic approaches to anaphoric interpretations (see **Pragmatic Presupposition**). In general these works share the view that anaphoric reference is interpreted by means of a range of inferential strategies. This is essentially a neo-Gricean approach, as evident in the work, particularly, of Huang (1994), who employs Gricean principles proposed by Levinson (1987) (see **Grice, Herbert Paul; Neo-Gricean Pragmatics**).

Much of the debate hinges on the very nature of pronouns and their contexts. Pronouns do not contain what is traditionally thought of as ‘descriptive material,’ and yet they are used to refer precisely to that material. This has led quite naturally to theories of anaphoric behavior broadly deemed

‘substitutional.’ Perhaps the most radical attack on these approaches was presented by Jones (1995), who declared the phenomenon of anaphora and its attendant substitution theories a ‘hoax.’ For Jones, reference is not an intrinsic property of particular language units and therefore not a property that some units have more than others. Broadly pragmatic, Jones’s theory sees reference as a contextualized communicative action expressed in and through the properties of an utterance as a whole. Since, for Jones, what is referred to by speakers is outside and beyond the means used to refer to it, there is no possibility of any linguistic constraints on reference. Such a radical view represents the ultimate pragmatic position, but most theorists have been content with a compromise, whereby linguistic elements routinely prompt a number of interpretive strategies. However, such a compromise is rarely satisfactory and often results in a weakened pragmatics, wherein what appears to be a contextual rule is in fact no more than a linguistic one, dressed up in the language of Gricean or neo-Gricean pragmatics (see **Metapragmatics**).

Furthermore, there seems to be evidence that anaphoric pronouns are not merely interpreted in a pragmatic fug of inferencing, but are, after all, subject to certain constraints. Jones’s view therefore throws too much onto context and pragmatics; after all, if there were no constraints or intralinguistic rules, we would not be able to make the right kinds of inferences (see **Context, Communicative; Constraint, Pragmatic**).

As Heim states:

... there are data which seem to point to the existence of tighter and somehow more ‘syntactic’ limitations on the range of reading that actually emerge (p. 165).

Deixis is much more easily subsumed under a pragmatic theory. Traditional accounts make a distinction between the indexical and symbolic meanings of deictic terms. The symbolic meaning of a deictic term might be said to be its semantic aspect, while the indexical meaning is its pragmatic aspect. For example, the expression *here* might be said to have a symbolic aspect roughly glossed as proximity to the speaker, while the indexical aspect would be the precise location to which *here* was referring. The terms ‘indexical’ and ‘symbolic,’ then, have much in common with the Fregean concepts of ‘reference’ and ‘sense’ (see **Frege, Friedrich Ludwig Gottlob**). But the semantic aspect is so vague in certain contexts that many have felt that it cannot really be said to have any bearing on interpretation. Nunberg (1993) in particular has shown that, just as the indexical meanings of deictic terms change according to the

contexts in which they occur, so too do the symbolic meanings (see **Indexicality: Theory**). This breaking down of traditional binarism has had important implications for pragmatic theory. Emphasis has shifted from the meaning and reference of terms in possible contexts to consideration of the cognitive methods that addressees employ in the interpretation of utterances. Pragmatic approaches have in general attempted to blur the line between deixis and anaphora, but the tendency to see one element (deixis) as essentially exophoric and the other (anaphora) as intralinguistic remains.

Dialogism, Bakhtinian

G S Morson, Northwestern University, Evanston, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

'Dialogism' (along with 'prosaics') is one of two commonly used cover terms to describe the main theories of the Russian scholar Mikhail Bakhtin (1895–1975) about language, literature, culture, and the psyche. The theories also occur in the works of Bakhtin's colleagues and disciples, Valentin Voloshinov and Pavel Medvedev, who tried to reconcile them with Marxism, which Bakhtin did not do (see **Bakhtin, Mikhail Mikhailovich; Voloshinov, Valentin Nikolaevich**).

Dialogism describes an approach to culture in terms of dialogue, but Bakhtin used the term 'dialogue' to mean different things over the course of his long career. The term was central to his early study of

Dostoevsky, *Problems of Dostoevsky's poetics* (1929), whose fifth chapter outlines a general theory of language in terms of dialogue. During the 1930s, Bakhtin developed his theory of language and applied it to his study of literary genres. He praised the novel as the most dialogic, and therefore the most realistic, literary genre. In the 1960s and 1970s, he extended some brief comments in his earlier works to suggest a dialogic approach to culture as a whole.

Because Bakhtin's usage of the term constantly changed, inconsistencies, sometimes amounting to flat contradictions, appear in his own writings and in those of his followers and explicators. 'Dialogic' in one sense may be opposed to monologic, but in another sense it may not allow for the existence of the monologic. Among Bakhtin's explicators, dialogue is often confused with Hegelian or Marxist dialectics, despite Bakhtin's explicit and vehement contrast of

the two concepts. It is therefore worthwhile to distinguish which sense of 'dialogue' one has in mind. Among the many that appear in Bakhtin's works, three principal usages stand out most clearly.

1. 'Dialogue' in the first sense describes a general approach to language. Bakhtin contended that linguists have been mistaken in taking the sentence as the fundamental unit of language. To mean anything, and be part of language as it actually exists, a sentence must be transformed into an utterance, which is a part of a specific dialogue. Language is a matter of people speaking to each other on specific occasions for specific purposes, and many features of language will be overlooked if one focuses on the sentence. To be sure, linguists, when necessary, "smuggle into" their analyses of sentences some features of 'dialogue,' but they do not fully understand 'dialogue' or take it as their point of departure.

In this use of the term, all utterances are, by definition, dialogic. Sentences, so to speak, hang in the air; they have the potential to become parts of a dialogue if they are 'embodied.' A particular person must say the sentence to someone for a particular reason at a given moment. If that person should use the same sentence (such as, *What time is it?*) on a different occasion, its meaning will be different. Sentences are repeatable, but utterances in dialogue are not, because each moment and each dialogic exchange differs from every other. Another way Bakhtin expresses this point is saying that utterances, unlike sentences, possess 'addressivity'; they must be addressed to someone in order to exist as utterances at all, and this act of addressing shapes them from the outset (see **Addressivity**).

Speakers do not first formulate sentences and then utter them, and listeners do not just happen to hear them and passively decode them. The dialogic exchange does not resemble the delivery of a letter by post or the encoding and decoding of a message in Morse code. Rather, the listener actively shapes the utterance from the beginning. The speaker takes into account the listener's status, knowledge, beliefs, and values; anticipates possible responses; and shapes his or her utterance accordingly. If the listener is present and begins to react visibly to the utterance (which may be much longer than a single sentence) while it is being uttered, the speaker may shift its tone, style, and choice of words as he speaks. In a real sense, then, the speaker and listener are co-creators of the utterance during each dialogue. The utterance belongs to the speaker alone only in a purely physiological sense.

Similarly, every dialogue is about something, and whatever it is about has been discussed before. The topic is 'already spoken about' and words sometimes

seem to carry with them the earlier contexts of their usage. At times, the word may be dense with remembered contexts, and the utterance has to weave its way among earlier uses, agreeing with some, parrying others, indicating ambivalent relations to many more. Thus, the dialogic aspect of utterances pertains not only to the present exchange in which they take part but also to the orientation of speakers and listeners to earlier dialogues on the same topic. Each dialogue is in dialogue with its predecessors.

Bakhtin understood the psyche to be largely linguistic in nature, by which he meant that we think in terms of dialogues. We address others silently, and the others who figure most prominently in our inner dialogues, the ones we address most often and whose imagined responses count the most, in large part define who we are. Moreover, some expressions prominent in our culture may exist within us as simply authoritative words that we hold at a reverential distance and do not question, whereas other ways of speaking are more or less appropriated by us until they become our own. We make ourselves by gradually choosing among the meaning-laden ways of speaking given by our culture.

Each dialogic exchange is unique, but dialogues fit into patterns. It would be impossible to define all the presuppositions about meaning, fact, and purpose that enter into every speech exchange, and so we use templates, or what Bakhtin calls 'speech genres,' to get started. Each speech genre, whether it defines the purchase of a railway ticket, the psychological novel, or the exchange in a psychoanalytic session, pertains to a specific kind of dialogue, which speaker and listener (or writer and reader) may modify in the course of using it. Any given language – say, English or Russian – contains not only grammar, syntax, and vocabulary, but also, if we conceive of language dialogically, a set of speech genres. Those genres differ from language to language, and so people who know a language from study in school may still find themselves misunderstood or uncomprehending because they do not know that language's speech genres. Genres change over time. They alter according to the pressure of many individual dialogues and so represent essentially cultural transitions. They are a drive belt from experience to language. Moreover, individual words may carry with them the 'aura' of the context in which they are typically used. What is often described as a word's 'connotation' is in fact the trace of a speech genre (see **Genre and Genre Analysis**).

2. 'Dialogue' in the second sense refers to a specific type of dialogue (in the first sense). In the second sense of the term, not all utterances are dialogic; some are 'monologic.' A monologic utterance is directly

oriented towards its topic and purpose. Although the words it uses may be shown to carry the traces of earlier dialogues, those traces do not constitute part of the utterance's 'task.' If heard, they would interfere with it. The speaker wants only one speech center, his own, to be heard and attended to. By contrast, we may (in the simplest case) cite someone else's words – the person before one or some generally known quotation – with an ironic intonation. In that case, the speaker has taken another's utterance and given a new semantic direction to it. The utterance's task depends on the listener hearing two speech centers, that of the original utterance and that of the present speaker. When an utterance depends on our sensing two speech centers in interaction, we have a 'double-voiced word,' and each double-voiced word is dialogic in the second sense. That is, within a single utterance, an entire dialogue resounds (*see Irony; Narrativity and Voice*).

Double-voiced words are immensely various. They are of course present in each case of reported speech, of covert or overt citation, and of stylization or parody. But they are much more widespread and various than that. An utterance may, so to speak, glance over its shoulder at a possible response and incorporate an ironic answer to that response. To understand such an utterance, we must see its double-voicedness. Double-voiced words figure in the psyche as well, and they complicate our inner speech (*see Reported Speech: Pragmatic Aspects*).

Drawing on Dostoevsky's novels, Bakhtin offers a catalogue of double-voiced words and mentions a number of them that occur in daily life. Each of these would be misunderstood if analyzed solely in terms of traditional linguistics, because their defining characteristic is the presence of two speech centers. Sometimes a cited word may even seem to overwhelm the citing one and bend it to its own purpose. Various forms of mental pathology may involve the activity of internalized hostile double-voicedness. An antipathetic other mocks our inner voice as we think.

In Bakhtin's view, the realist novel makes the most extensive use of dialogue in the second sense. Novels dialogize whole world views, as they are represented by the particular ways of speaking of given professions, generations, subcultures, and many other groups. Bakhtin calls the many different, value-laden ways of speaking in a given language 'languages of heteroglossia.' Novels dialogize heteroglossia, and so force the differing parts of a culture to confront each other. An apparently straightforward passage of novelistic prose may in fact contain complex implicit dialogues. Though spoken in the third person, the passage may in fact paraphrase what a given character

would say in her own distinct language; that paraphrase may be implicitly subjected to an authorial commentary. Or we may hear how those words would sound to another character not present and so detect dialogues that might happen. If these characters' ways of speaking also reflect different languages of heteroglossia, then whole world views may be brought into interaction. Prior to Bakhtin, such effects, though sensed, could only be described by the catch-all term 'irony.' The concept of dialogue thus allowed Bakhtin to demonstrate the complex art behind novelistic prose and one reason that novels seem to offer both subtle social commentary and an especially rich sense of the individual psyche (*see Literary Pragmatics; Pragmatics of Reading*).

3. 'Dialogue' in the third sense refers to a world view. If we imagine that what happens in an especially rich dialogue characterizes the world as a whole, we may understand life itself dialogically. To live means to engage in dialogue, and all cultural activity is a giant symposium. In the richest dialogues, the interaction of speakers may lead to insights that neither had before, and so dialogue may be genuinely creative. It manifests 'surprisingness' (*see Conspicuity*). That is, it is one source of the world's indeterminism. Bakhtin thus used dialogue as an image of why a deterministic view of life is mistaken and why free choice is real. Dialogue therefore became part of his lifelong agenda to demonstrate the meaningfulness of ethical responsibility (literally, 'answerability' in Russian). If the world were simply the execution of ready-made causal chains, it would contain no freedom and so no responsibility. It would be a dead thing. But dialogue belies this view of the world and allows us to see that nothing in it is final or already given. Because it allows for the genuinely new and surprising, dialogue makes the present moment matter. In one rather vague passage, Bakhtin states that there is even a kind of truth that is essentially dialogic. Such truth cannot be paraphrased as a single, monologic utterance. The Socratic dialogues partially represent this sense of truth and it is fully present in Dostoevsky. Numerous critics have pointed out that this third concept of dialogue relates closely to Bakhtin's theology, to the dialogue between God and man, and perhaps, to the dialogue among the persons of the Trinity. This interpretation may be rejected by one who still accepts Bakhtin's account of dialogue in the first sense and second sense.

Discourse Anaphora

F Cornish, University of Toulouse-Le Mirail, Toulouse, France

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Discourse anaphora is a means of managing the memory representation of the discourse being constructed by the speech participants on the basis of a cotext as well as a relevant context (for further details of this view, see Cornish, 1999, 2003; but *see also* Deixis and Anaphora: Pragmatic Approaches in the present volume, for somewhat different perspectives). Where discourse is concerned, it is clear that not all referents will have been introduced via an explicit textual antecedent; it is also possible for them to be evoked 'obliquely' in terms of an association or a (stereotypical) inference of some kind (see especially example (1), which follows).

This article takes what might be termed a 'discourse – cognitive' view of anaphoric reference, rather than

a textual–syntactic one. The use and interpretation of nonbound anaphors – that is, anaphoric expressions whose interpretation is not determined primarily by features of the clause in which they occur – require not only a relevant cotext as well as context, but also, crucially, a psychologically salient representation of the discourse evoked via what in previous work I have called the antecedent-trigger (an utterance token, gesture, or percept). See the section titled 'The Antecedent-Trigger' for a discussion of this term.

Some Useful Concepts and Distinctions in the Study of Indexical Reference: 'Anaphora,' 'Deixis,' and 'Textual/Discourse Deixis'

Let us start by drawing the more fundamental distinction between the dimensions of *text* and of *discourse* (see *Understanding Spoken Discourse*). Very briefly, *text* refers to the ongoing physical, perceptible trace

of the discourse partners' communicative or expressive activity. This includes not only the verbal content of an utterance, but also prosody, pausing, semiotically significant gestures (nonverbal signals), and of course punctuation, layout, and other graphic devices in the written form of language (see **Text and Text Analysis**). The addressee or the reader exploits these textual features in order to infer the *discourse* being coconstructed by the participants. *Discourse* in this sense refers to the hierarchically structured product of the constantly evolving sequence of utterance, illocutionary, propositional, and indexical acts jointly performed by the discourse partners (see, for an illustration, representation (7) of the discourse corresponding to text (5)). This product is, of course, partly determined by the context invoked (see **Text World Theory** for a similar conception of discourse).

Discourse anaphora, then, constitutes a procedure (realized via the *text*) for the recall of some item of information previously placed in discourse memory and already bearing a minimal level of attention activation. It is essentially a procedure for the orientation of the interlocutor's attention, which has as essential function the *maintenance* of the high level of activation that characterizes a discourse representation already assumed to be the subject of an attention focus by the interlocutor at the point of utterance. It is not only the anaphoric expression that is used (typically, a third-person pronoun) that realizes (discourse) anaphora, but also the clause in which it occurs as a whole. This predicational context acts as a kind of 'pointer,' orienting the addressee toward the part of the discourse representation already cognitively activated and which will make it possible to extend in terms of an appropriate coherence relation (see Kleiber, 1994: Ch. 3).

- (1) [Fragment of dialogue in film:] Woman: "Why didn't you write to me?" Man: "I did . . . , started to, but I always tore 'em up." (Extract from the film *Summer Holiday*. Figure (5.5) from Cornish F (1999). *Anaphora, Discourse and Understanding. Evidence from English and French*. Oxford: Clarendon Press. 157. By permission of Oxford University Press (URL www.oup.com). Also reprinted as example (6d), p. 204 from Cornish (2005) by permission of John Benjamins Publishing Company.)

In (1), an instance of indirect anaphora, it is the illocutionary point of the woman's initial question, which bears on the nonexistence of a letter or letters that she had expected the man to write to her, together with the lexical-semantic structure of

the verbal predicate *write* (in the sense "engage in correspondence"), that provides an interpretation for the unstressed pronoun 'em in the third conjunct of the man's reply. The example clearly shows the extent to which inferences based on existing discourse representations, lexical, and general knowledge are mobilized in the operation of discourse anaphora, which clearly does not require the copresence of an explicit textual antecedent, under the traditional cotextual account of anaphora, in order to exist (see also Blackwell, 2003, in connection with a study of Spanish conversations and spoken narratives, and Ziv, 1996).

Here is an example involving different possible continuations of the antecedent-trigger predication in terms of distinct anaphoric predications:

- (2) Jason_i witnessed a terrible accident_j yesterday_k
at the Dunton crossroads_l. He_i was very
shaken/*It_j* resulted in two deaths/*#It_k* was
dull and overcast/*?#It_l*/The place_l is a known
danger-spot.

Note: Subscripted letters indicate identity or otherwise of the intended referents of the expressions so marked. In (2), the first two argument referents introduced ('Jason' and 'the terrible accident Jason witnessed the day before the utterance of (2)') may be naturally continued via unaccented pronouns – but not the scenic referent 'the day before utterance time,' nor (or at least, not as easily as with the first two entity referents evoked) 'the Dunton crossroads,' which is expressed by an adjunct and which serves as a locative frame of reference for the situation evoked as a whole (see also the point made in regard to certain natural Spanish conversational data by Blackwell, 2003: 118, 122–3). The slashes here are meant to indicate alternative continuations of the initial sentence. The crosshatch preceding an example is intended to signal that, as a potential utterance, it is unnatural in the context at hand. Example (2) is intended to be discourse-initial, and not part of an earlier, ongoing discourse.

Deixis, on the other hand (see **Deixis and Anaphora: Pragmatic Approaches**), is a procedure that relies on the utterance context to redirect the interlocutor's attention toward something associated with this context (hence that is potentially familiar to him or her), but to which she or he is assumed not already to be attending. As Kleiber and other pragma-semantics have observed, *deixis* causes a break in the continuity of the discourse at the point where the deictic procedure is used, so that in effect the interlocutor is invited to 'step out' of this discourse context to grasp a new referent in terms of the current situation of utterance – or, alternatively, another

aspect of a same referent, which has already been focused upon. So deixis serves to introduce a new referent into the discourse, on the basis of certain features of the context of utterance.

Now, *textual* as well as *discourse deixis* provide a transition between the notions of deixis and anaphora, because they consist in using the deictic procedure to point to part of a pre- or postexisting textual or memory representation, but which is not necessarily highly activated. The interlocutor will therefore need to exert a certain cognitive effort in order to retrieve it. This interpretative effort will involve constructing an 'entity,' on the basis of the discourse representation in question, in order for it to be the subject of a predication, an anchor for the introduction of new information. Where there is a difference in topic-worthiness between the representation introduced by a trigger and the intended referent, the *discourse-deictic* and not *anaphoric* procedure must be used, as in (3), an attested utterance:

- (3) [End of the words of welcome uttered by the director of the Language Centre, at the start of a conference, University of Edinburgh, 19 September 1991] "... We intend to record the guest speakers, so *these* will be available to participants at the end of the Conference ..."
- (Example (20) in Cornish, 2005: 212.)
(Permission to reprint granted by John Benjamins Publishing Company.)

In order to access the referent targeted via the proximal demonstrative pronoun *these* (namely, 'the recordings of the guest speakers' papers'), the hearer will have to draw an inference of the type: "If the guest speakers' papers are recorded at time t_0 , then at time t_n ($t_n > t_0$), there will be recordings of these papers." Unlike the indirect referent in (1) and the first two more 'direct' ones in (2), here the implicit referent has not attained the status of a potential *topic* (see **Thetic-Categorial Distinction and Topic and Comment**) by the time the initial clause is processed, for it is 'the guest speakers' that enjoys this status at this point. So it is predictable that the elaborative *so*-clause that immediately follows will continue to be about these entities. The demonstrative pronoun *these* in (3) directs the hearer's attention toward a referent that she or he must create on the basis of the representation introduced via the initial conjunct, as well as in terms of his or her knowledge of the world. So it is an instance of *discourse deixis* rather than of *anaphora*. Indeed, the (anaphoric) personal pronoun *they* in its place would have maintained the situation evoked via the initial conjunct, resulting in the retrieval of the only salient topic-worthy entity within it,

'the guest speakers' – an interpretation leading to quite severe incoherence here.

Three Essential Ingredients of the Operation of Discourse Anaphora: 'Antecedent-Trigger,' 'Antecedent,' and 'Anaphor'

The Antecedent-Trigger

This is not necessarily an explicit, textual expression (a phrase of some kind). It may also be a percept or a nonverbal signal (see Cornish, 1996, 1999: ch. 4). In (1) it is the illocutionary point of the woman's initial question, in conjunction with the use of the verb *write* that triggers the discourse representation in terms of which the pronoun *'em* refers, whereas in (2) it is the use of the descriptive noun phrases *Jason*, *a terrible accident*, and *the Dunton crossroads*. The broader notion of 'antecedent-trigger,' in relation to the traditional, canonical textual 'antecedent' of normative written prose, which is required to be morphosyntactically and semantically parallel to the anaphor, is useful in that it enables us to include both exophora and indirect anaphora (see example (1)) within the purview of anaphora *per se* – of which both these phenomena are instances (see also Cornish, 1999: 41–3).

The Antecedent

This is a psychologically salient discourse representation in terms of which the anaphor refers or denotes. As this characterization suggests, it is a unit of *discourse*, not of *text* (see the distinction drawn earlier) and may be constructed via direct interpretation of the cotext in terms of a relevant context or in terms of the context alone in conjunction with relevant aspects of mutual knowledge, or in terms of inferences from either of these. See, as an example, the informal description of the antecedent of the unstressed pronoun *'em* in (1): 'the set of unfinished, torn and unsent letters which the man had begun writing to the woman.' See also Dahl and Hellman (1995), Langacker (1996), van Hoek (1997), and Cornish (1999: 44–7). A given antecedent-trigger may give rise to several distinct 'antecedents' (in this sense), as a function of the possible drawing of inferences, of what is predicated of the former's referent, or of the functioning of the type of anaphor chosen to target it. Sample (4a, b) provide examples, where the antecedent-trigger *one of the new Toyota models* in the first sentence of (4a) gives rise to different 'antecedents' targeted by the pronouns *they*, the *it* in the second anaphoric continuation, and *one*; whereas the entire initial sentence acts as antecedent-trigger

for the antecedents created via the anaphors *that* and the *it* in the final anaphoric continuation in this example:

- (4a) John bought one of the new Toyota models yesterday. *They* are really snazzy cars/ *It* is standing outside his front door/ Mary bought *one* too/At least, *that's* what he told me/*It* took only half an hour to complete.
- (4b) "The grouse season begins today, and *they're* being shot in large numbers" (*Today Programme*, BBC Radio 4, 10.12.04)

The Anaphor

This is a referentially dependent indexical expression. The relation is not exclusively between antecedent-trigger and anaphor (except in the case of metalinguistic occurrences, as in this example: A: *Psephism was much in vogue in those times*. B: *What does that mean?*: but these in any case, as Lyons (1977) points out, are instances of *textual deixis*). First, then, the anaphor refers, not to its antecedent(-trigger), but in terms of whatever its antecedent(-trigger) refers to (see Lyons, 1977, vol. 2: 660). Second, the discourse referent evoked via the antecedent-trigger is not necessarily the same at the point of retrieval via the anaphor as it was at the point of introduction: minimally, what will have been predicated of the referent concerned within the antecedent-trigger predication (and potentially within subsequent predications) will have altered that referent's representation – perhaps even radically. Third, it is not simply the anaphor on its own that retrieves the (updated) discourse referent at the point where it occurs in the cotext, but the anaphoric (or 'host') predication as a whole: compare the anaphoric continuations in examples (2) and (4a) in particular in this respect. So what is predicated of the referent of the anaphor acts as a filter, ruling out theoretically possible referents or denotata, and as a pointer, targeting and selecting a salient discourse representation that is compatible with what is predicated of the anaphor's referent (see also Yule, 1981; Dahl and Hellman, 1995).

As we shall see in analyzing text (5) in the next section, there is a variety of types of anaphor – zero forms; ordinary pronouns; demonstrative pronouns; reduced proper names; demonstrative, definite, and possessive full NPs; ellipses of various kinds; and so on – which each have distinct indexical properties. As such, they each function to establish different kinds of discourse anaphoric structures and are each sensitive to specific types of discourse context and function. See Cornish (1999: 51–68) for some discussion. On the use of demonstratives in narrative discourse, see in particular Himmelmann's (1996) typological study.

The Text – as Well as Discourse – Sensitivity of Discourse Anaphora

The text we are going to analyze for illustration is taken from a British newspaper, *The Guardian* (1 July 1998, p. 3), reproduced under (5) (for convenience in the analysis that follows, the paragraphs are each numbered in the left-hand margin).

(5) ***Monet waterlilies set £20m record***
Luke Harding

1. A painting of the most famous garden in the history of art last night sold for £19,801,500, shattering all records for a work by Claude Monet.
2. Two frenzied telephone bidders pushed the price for Monet's *Waterlily Pond and Path by Water* to almost £20 million at Sotheby's, suggesting that good times are back again for the fickle art market.
3. The price, reached after six minutes of bidding, comfortably shatters the previous £13 million record for a painting by the artist. *Waterlily Pond* is now the most expensive Impressionist work sold by a European auction house since 1990. Sotheby's had estimated the sale price more modestly at £4–£6 million.
4. The oil painting, executed in 1900, was acquired by a private British collector in 1954 and has not been shown in public since then.
5. The identity of the buyer is a mystery. "We are still totting up the figures for the total auction," a jubilant Sotheby's spokeswoman said last night. "It's been a very very good night."
6. Monet was passionate about flowers and intrigued by landscape architecture. In 1893 he purchased a plot of land which adjoined the rural house in Giverny, near Paris, where he had moved 10 years earlier. A small stream ran through the plot, and Monet turned the garden into a horticultural paradise.
7. Monet worked tirelessly during the summer months, producing 12 pictures in 1899 and six in 1900. The oil sold last night shows the left section of his water garden, with the Japanese-style footbridge and path gently curving through patches of purple irises and tall grass.
8. "It took me some time to understand my waterlilies," Monet said in a conversation with the author Marc Elder in 1924. "All of a sudden I had the revelation of how enchanting my pond was. Since then I have had hardly any other subject." *Waterlily Pond and Path by the Water* is now the 11th most expensive ever painting sold at auction. Its sale price is easily eclipsed, though, by another work completed just nine years earlier – *Portrait du Dr. Gachet* – by a then little-known artist, Vincent Van Gogh, which went for \$82,500,000 (£55 million) in 1900.

9. *Last night's sale follows a gradual recovery in the art market – unlike the overheated boom of the late 1980s, where it was focused in just one or two areas. Recent sales of Impressionist and Old Master works have been encouraging – despite allegations that many of Van Gogh's best-known works are fakes* (Example (8) in Cornish, 1998: 30–31). (Permission to reprint granted by *Guardian Newspapers* and *Cahiers de Grammaire*.)

In this text, there are several 'topic chains' (see Cornish, 1998, 2003 for further details). A topic chain is a sequence of mainly anaphoric (referentially dependent) expressions within a text that retrieve the same referent, which is thus the subject of several predications for a segment of the text. This referent may have been introduced explicitly via a *referentially autonomous* expression, such as a full proper name, an indefinite NP, or a full definite NP. This is the 'head' of the chain, the anaphoric expressions retrieving its referent then being the 'links.' We will adopt Dik's (1997: 218) definition of topic chains (what he calls 'anaphorical chains') in recognizing three theoretical discourse-functional positions within them: (1) the head of the chain, which introduces the topic referent into the discourse; (2) a second-link position (only exploited in 'macro'-topic chains), whose function is to 'reconfirm' the installation of the topic referent in question – that is, it has an essentially addressee-oriented function; and (3) a third position, which may be multiply filled, consisting of purely anaphoric retrievals of the topic referent whose function is to maintain the high-attention focus now accorded (or assumed to be so accorded) to that referent by the addressor. By the third link, then, the referent retrieved is taken as enjoying full topic status in the discourse.

The four most important topic chains in text (5) are the following: (1) the one dealing with the article's overall topic, the painting by Monet which had just been sold by auction for a record price; (2) the one bearing on the price fetched by the sale; (3) the one having to do with the artist himself; and finally (4) the one dealing with the plot of land that he had bought at Giverny in 1893, of which the stream that flowed through it served as a model for his painting. These chains are made up of the following successions of expressions:

1. *A painting of the most famous garden in the history of art ... Monet's Waterlily Pond and Path by Water ... Waterlily Pond ... The oil painting ... ø ... The oil sold last night ... Waterlily Pond and Path by the (sic) Water ... Its ...;*
2. *£19,801,500 ... the price for Monet's Waterlily Pond and Path by Water ... The price ... the sale price ... Its sale price ...;*

3. *Claude Monet ... Monet ... the artist ... Monet ... ø ... he ... he ... Monet ... Monet ... ø ... his ... Monet;*
4. *A plot of land which adjoined the rural house in Giverny, near Paris, where he had moved 10 years earlier ... the plot ... the garden ... his water garden*

Let us represent these four topic chains schematically, using the abbreviations 'R-A' for 'referentially autonomous expression' and 'R-NA' for 'referentially nonautonomous expression,' as follows ('H' = 'Head of chain,' 'L2' = 'Link-2,' and 'L3' = 'Link-3'):

(6) *Schematic representation of the four topic chains in (5)*

- **Topic Chain 1:** H: R-A; L2: R-A; L3: R-NA, R-NA, R-NA, R-NA, R-A, R-NA.
(*'the painting by Monet'*)
- **Topic Chain 2:** H: R-A; L2: R-A; L3: R-NA, R-NA, R-NA.
(*'the sale price reached by the painting'*)
- **Topic Chain 3:** H: R-A; L2: Ø; L3: R-NA, R-NA, R-NA, R-NA, R-NA, R-NA, R-NA, R-NA, R-NA, R-NA.
(*'Claude Monet'*)
- **Topic Chain 4:** H: R-A; L2: Ø; L3: R-NA, R-NA, R-NA.
(*'Monet's garden'*)
(Item (9) in Cornish, 1998: 32, slightly adapted.)
(Permission to reprint granted by *Cahiers de Grammaire*.)

This representation points up the fact that referentially autonomous and anaphoric expressions do not occur indiscriminately in any position within a chain. For apart from the autonomous expression that occurs in fifth position within the link L3 in chain 1 (*Waterlily Pond and Path by (sic) Water*), autonomous referring expressions always occur in the central positions within chains (positions H and L2); whereas anaphoric expressions appear only within link-position L3. See Ariel (1996) on the distinction between referentially autonomous and non-autonomous indexical expressions (particularly as far as the distinction between full and reduced proper nouns is concerned).

Interestingly, it is precisely in the two topic chains that are intuitively the most central to text (5) as a whole (namely, chains 1 and 2) that we find link L2 realized by an autonomous expression. The other two chains (3 and 4), where this same link is by hypothesis unfilled, evoke referents that are subsidiary within this discourse in relation to the referents developed by chains 1 and 2: the article deals, after all, with the particular work by Monet as well as with the record

price it fetched in auction, rather than with the artist or his garden as such. Furthermore, the representation in (7) (following) of the discourse structure associated with (5) shows that although chains 1 and 2 are set up within central discourse segments (paragraphs 1–3, 5, 8b, and 9), chains 3 and 4 are restricted to background, subsidiary segments (the segments corresponding to paragraphs 4 and 6–8a). So it is not surprising that the last two topics should not have required an L2 link for their installation within the discourse.

Let us look now at the relationship between the occurrence of an expression realizing a given link in a chain and the discourse function of the unit in which it occurs, in terms of the structure of the discourse as a whole. Schema (7) represents the structure of text (5) as discourse (indentations indicate subsidiary segments):

(7) *Discourse structure corresponding to text (5)*

1. [Para 1: **Introduction of the global discourse topic**, the painting by Monet and its record price reached at an auction in London]
2. [Para 2: **Continuation** of the sequence of events surrounding 1]
3. [Para 3: **Development on the record price** reached by the sale of the work]
4. [Para 4: **Background segment** on the history of the painting, from its inception to the present]
5. [Para 5: **Return pop to the central topic**.
Introduction of two local topics (not developed in the remainder of the text): the buyer's identity, and the calculation of the total price of the sale]
6. [Para 6: **Flashback** to the subject matter of the painting and its origin: the purchase by Monet of a plot of land near his country house in Giverny – the inspiration behind the work. No reference to the painting as such]
7. [Para 7: **Development of this background topic**: what the painting shows of the garden]
- 8a. [1st half of Para 8: **Continuation of the topic of Monet's inspiration** drawn from his garden at Giverny]
- 8b. [2nd half of Para 8: **Return to the central topic of the record price of the painting** and comparison with the astronomical price reached by another painting of the same period]
9. [Para 9. **Conclusion: Extrapolation to the art market in general** – the recovery of the art sale market precipitated by this auction. No reference to Monet's painting]
(Item (10) in Cornish, 1998: 34)
(Permission to reprint granted by *Cahiers de Grammaire*.)

The structure of the first two of the four topic chains in (5) in this respect is as follows. The title of the article already sets up the global theme, the sale of Monet's painting *Waterlily Pond and Path by Water*

and the record price it fetched. In the introductory paragraph, this dual aspect of the global theme is made explicit in a complex sentence. As an introductory sentence-paragraph, it has a 'thetic' character, where the information it presents to the reader is entirely new (see **Thetic-Categorial Distinction**).

The second paragraph is an elaboration of the situation established by the first, dealing more specifically with the price of this sale at auction; but it also serves to *identify* the painting by Monet, which is the topic of the first paragraph. This cannot be an instance of *cataphora*, where the antecedent-trigger follows the 'cataphor,' for all that, given the referentially autonomous character of *both* nominal expressions used here (full indefinite NP and full proper name); so the referential dependency of anaphor on 'antecedent-trigger' does not obtain – that is, we have *coreference* without *anaphora* in the strict sense here. The use of two indexically strong (referentially autonomous) expressions at this point – *Monet's Waterlily Pond and Path by Water* and *the price for Monet's Waterlily Pond and Path by Water* – is no doubt motivated by the concern to promote their referents to global topics within the article, following their brief introduction in the initial paragraph.

The third paragraph continues this theme of the price fetched by the sale of the painting. Note that the two references to the dual global topics of the article are made via lexically explicit NPs (a reduced proper name for the painting (*Waterlily Pond*) and a definite, also reduced, NP for its price (*the price*)), and not via pronouns. (The fact that these are reduced NPs means that they are not referentially autonomous, but are potentially anaphoric, like pronouns.) See Geluykens (1994) on the question of anaphoric 'repairs' in spoken interactions, where the speaker mis-assesses their addressee's current attention state, and uses a reduced indexical form type (a pronoun of some kind), which she or he immediately corrects to a fuller form (a definite or demonstrative NP or a proper name). There are two reasons behind the use of *the price* as subject of the initial sentence of this third segment of the discourse: first, this reference is followed immediately by a nonrestrictive relative clause in apposition, a position from which unaccented pronouns (here *it*) are excluded (this is also the case with the lexical NP *the oil painting* in paragraph 4); and second, the repetition of the definite article and of the lexical head of the complex NP, which were used in the previous paragraph to 'topicalize' the referent at issue, signals at the start of this new segment that it will continue to be about it. In other words, the referent in question, though topical, is nonetheless reevoked at the very beginning of a *new* discourse segment and no longer within the one in which it

was originally topicalized. See Fox (1987) in this respect, who argued that repeated proper nouns in English spoken and written texts may have this function, and also Blackwell (2003) in relation to her spoken Spanish data.

Similarly, the use of a proper noun, albeit reduced (*Waterlily Pond*), at the point in this segment where this reference occurs, is made necessary by the evident need to distinguish this referent from the other central referent, which has already been evoked in this paragraph ('the painting's sale price'), but which enjoys an advantage over it in terms of topic-worthiness at the point where the reference is made. The pronoun *it* used in its place would certainly have retrieved this latter referent, and not 'the painting' as such. This fits in well with what is stated by Levinson's (1995) "M-principle" (see also Huang, 2000: 208), to the effect that the use by a speaker of a phonologically and lexically more substantial expression where a more attenuated one could have been used in its place is normally intended and interpreted as *not* meaning the same as if the more unmarked expression had been used (see **Deixis and Anaphora: Pragmatic Approaches** for further details of this account).

As for the two references to these two macrotopics throughout paragraph 4, where the focus switches to background considerations relating to the central theme, the first is made via a definite lexical NP (*The oil painting*, in initial subject position of the segment) and the second by means of a null form, the ellipsed subject of the second conjunct of the clause, which realizes this segment. The motivation behind the use of the former expression type at the beginning of this segment is exactly the same as that of its counterpart *the price* in the same position at the start of the previous paragraph. Because it is followed by a nonrestrictive relative, a pronoun could not have occurred in its place; but even if one could, it would be excluded for reasons of anaphoric ambiguity: for the pronoun *it* here – leaving aside what is predicated of the referent of this expression in this context – would have retrieved the referent 'the sale price' evoked by the immediately preceding clause.

Paragraph 7, which falls together with paragraphs 6 and the first half of 8 in a background discourse segment, includes a reference to the painting, a reference that reevokes at the same time the event of the sale on June 30 (*the oil sold last night*). Once again, we have to do here with a definite (elliptical) NP; and just as in the previous cases, the reason for it is the existence of comparable referents that are in competition in terms of topichood. The first half of paragraph 8 (8a) continues the theme of the subject

of the painting ('Monet's garden'), a theme that is abruptly interrupted in the middle of this paragraph by the opening of a segment returning to the macrotopic of the record sale price reached by this painting at auction at Sotheby's.

Now, it is precisely by means of a full proper name that this transition to a segment dealing with the circumstances of the sale of the painting is carried out. As such, we can hypothesize that it corresponds to what Dik calls a *resumed topic*. It is this particular marked discourse function realized via this referentially autonomous expression that motivates its exceptional filling of the 'anaphoric' L3 link in this macrotopical chain (recall the structure of Chain 1 given in schema (6) earlier). Once its topic status has been reestablished within this new segment – which does not correspond this time to the start of a new paragraph in terms of textualization (see the *text/discourse* distinction mentioned earlier in the second section) – the next (anaphoric) reference may be realized by means of an unaccented pronoun: in this case, by the pronoun contained in the possessive determiner *Its*.

Conclusion

As we have seen in connection with text (5) in particular, the occurrence of different types of nonautonomous, potentially anaphoric expressions in a text is in large part determined by the discourse function of the unit of discourse corresponding to the textual segment in which that expression appears, as well as by its position within that segment. In the case of written newspaper articles of the kind seen in (5) at least, it is clear that initial position within a unit is reserved for lexically based NPs (reduced proper nouns and definite NPs, as well as demonstrative ones), whatever the degree of topicality and accessibility their intended referent may enjoy at that point; unaccented pronouns and of course null pronouns are virtually excluded from such positions, because they serve to mark the continuity of the attention focus established prior to their occurrence. We have also seen how the copresence of competing referents in the immediately prior cotext may favor the use of an indexically stronger form type than a pronoun or a null anaphor in order to avoid unintended anaphoric continuities.

Discourse anaphors, in sum, are sensitive to the hierarchical structure of the discourse that may be assigned to a given text, in conjunction with an appropriate context, and their choice by a speaker or writer is clearly a function of his or her ongoing assessment of the conditions under which their addressee or reader will be operating at the point of use. In the case of discourse anaphors, it is clear, in Dahl and Hellman's (1995: 84) colorful words, that

their ‘antecedents’ “aren’t just sitting there, waiting to be referred to, but rather ha[ve] to be created by some kind of operation”: this is a reflex of the fact that anaphora operates within the dynamic, ongoing construction of *discourse*, rather than exclusively in terms of the more static dimension of *text*.

Discourse Markers

J R Trillo, Universidad Autónoma de Madrid, Madrid, Spain

© 2006 Elsevier Ltd. All rights reserved.

Discourse markers can be defined as those elements, such as *you know*, *I mean*, *well*, *oh*, *m*, *you see*, *look*, *listen*, that have a distinct prosodic entity, tend not to have a specific semantic meaning, and contribute to scaffold the pragmatic coherence of interaction (see **Scaffolding in Classroom Discourse**). Broadly speaking, discourse markers have often

been described by their absence of traditional linguistic properties, since neither their use nor their meaning seem to resemble any of the traditional linguistic categories. In fact, these elements have been typically discarded from rigorous linguistic studies, and in different languages have been assigned the general vague name of ‘particelle’ (Italian), ‘fillers’ (English), or ‘muletillas’ (Spanish) – both the English and the Spanish terms evidence these markers’ function of ‘filling’ or ‘supporting’ discourse. In some sociolinguistic domains, discourse markers were marginalized because they were traditionally attributed to

incompetent and incoherent speakers of a language (Watts, 1989).

Schenkein (1972) and Jefferson (1978) were among the first that became convinced of the need to study these vague elements that seem to distort syntax and have a multiplicity of undefined meanings. As an instance, consider how Dik (1989: 45) characterized these elements as ‘extra-clausal constituents’; their role in natural language was described as follows: “*any natural language text can be exhaustively divided into clauses and extra-clausal constituents ... which are neither clauses nor part of clauses.*” In other words, discourse markers, for this author, belong to the realm of spoken language and need to be studied only with reference to the parameters of spoken language.

In the 1980s and early 1990s, some authors studied the general presence of discourse markers in several languages, with no special reference to any grammatical or syntactic model. Thus, for instance, Vicher and Sankoff (1989) described discourse markers in contemporary French; Bazzanella (1990) did the same for contemporary Italian, and Fraser Gupta (1992) for Singapore colloquial English. Other studies delved into the use of a specific discourse marker in a language, giving a full description of its different functions; cf., for example, Tognini-Bonelli (1993) on ‘actually’ in British English.

Since then, several authors have tried to name, classify, and describe the nature and function of these seemingly ‘elusive’ elements. In my opinion, there are three main approaches to the study of discourse markers: the conversational, the grammatico-syntactic, and the discourse-cognitive.

The conversational approach concentrates on the role of discourse markers in the structure of conversation. For example, Schegloff (1984), who called them “continuers,” stated that they are used by the speaker to show the listener that his/her speech forms a coherent whole in progress. In the same vein, Schifffrin (1987: 31) provides the following definition: “markers are sequentially dependent elements that bracket units of talk.” Both authors (along with others) agreed on the essentially spoken nature of these elements; from their studies, one is led to conclude that discourse markers are better analyzed from an interactional than from an ideational perspective (following Halliday’s (1994) macrofunctions of language) (see **Systemic Theory**). In fact, Schifffrin (1985: 281) pointed out that: “discourse markers ... help speakers express interactional alignments toward each other and enact conversational moves”; elsewhere she stated (Schifffrin, 1987) that the presence of discourse markers in a conversation helps the mechanics of turn-taking, the organization of speech

acts, the structuring of discourse ideas, the interactive structure of participants, and the presentation of information.

The second model corresponds to the grammatico-syntactic approach to discourse markers. Among others, Knott and Dale (1994: 45) described discourse markers as a “reasonably homogeneous group” that tends to be formed by “*simple* linguistic expressions [their italics] ... that have become simplified because they correspond to constructs that are in continual use when we process text.” In their description of the elements that can function as ‘cue phrases’ (the authors’ term for discourse markers), they enumerate coordinators, subordinators, conjunct adverbs, and phrases that take sentential complements (e.g., ‘it follows that,’ ‘it may seem that’). Also following this approach, in a comprehensive account of discourse markers, Fraser (1999: 938) explored the characteristics of these elements; discourse markers “impose a relationship between some aspect of the discourse segment they are a part of, call it S2, and some aspect of a prior discourse segment, call it S1.” In other words, this author identified discourse markers with the elements that signal a two-place relationship between adjacent discourse segments, e.g., *therefore*, *however*, *and*, etc., and discards other elements that he calls “commentary pragmatic markers” (e.g., *frankly*), ‘focus particles’ (e.g., *even*), ‘pause markers’ (e.g., *hum*, *well*), and interjections (e.g., *oh*). In my view, commentary pragmatic markers, and especially the latter two categories (pause markers and interjections) are the most outstanding and most frequently encountered in speech, because they are responsible for the scaffolding of interactional meaning in conversation. In fact, Fraser (1999: 943) considered that the three basic features of discourse markers are the following: they “do not constitute a separate syntactic category,” their meaning is “procedural not conceptual” (1999: 944) and, “every individual discourse marker has a specific, core meaning” (1999: 945). This view somehow contradicts Schifffrin’s (1987: 314) argument that not all markers have meanings; Fraser specifically mentioned the markers *oh* and *well* which, incidentally, are very common in English.

This apparent contradiction derives, in my opinion, from the fact that both the conversational and the grammatical-syntactic approach present a static view of discourse markers. By *static*, I mean that these approaches try to apply traditional linguistic parameters to a phenomenon that evades classical labeling and analysis. In my view, there are several issues to consider in this respect: first, it is not possible to discard from this category all the elements that

serve to scaffold interaction in conversation and only accept those that fulfill certain syntactic parameters (as Fraser does), and second, it is not possible to say that some of these elements have meanings and others do not (as Schiffrin suggests).

To describe the phenomenon of discourse markers, I propose what I call a discourse-cognitive approach: discourse markers are elements that fill the discursive and cognitive slots that spoken language needs in order to weave the net of interaction. This dynamic approach is geared to the description of the discourse and the cognitive status of the markers (Romero Trillo, 1994, 2001), but does not limit them to a closed-class repertoire. The approach intends to account for the two main issues at stake: the issue of a 'core meaning' for each marker, and the nature of an 'accepted' repertoire of discourse markers in each language. As to the first, the question of the core meaning poses many problems, since each element may appear in such a multiplicity of functional contexts, and with such a varied array of meanings, that it is very difficult to assign a core meaning, especially in the case of pause markers and interjections. Second, with regard to the elaboration of an accepted repertoire, it is my belief that what we find in discourse is not just a series of discourse markers; rather, we are dealing with discourse slots (functions), where any element – provided it fulfills several conditions related to context and prosody – can function as a discourse marker. In other words, the phenomenon of discourse markers shows that spoken interaction needs to have a pragmatic skeleton, consisting of such discourse slots, that holds the communicative force of the interaction together. The slots are filled by elements that may vary according to regional, ideolectal, or sociolinguistic features within one and the same language.

Due to this multiplicity of conditions that determine the choice of an element (multiplicity of functions and multiplicity of elements realizing each function), the challenge is to find a principled method of selection and a corresponding analysis of this phenomenon. In other words, how can we decide about the appropriateness of the meaning of an element in a specific discourse slot? What are the contextual interactions between the discourse marker and the slot in which it occurs?

When one looks at the elements that function as discourse markers, it becomes immediately clear that there are elements whose meaning is clear: *you know*, *I see*; alongside with them, we find other elements whose meaning it is difficult to trace: *mhm*, *aha*. This inclusion of discourse markers that have no apparent meaning or grammatical characterization, but play a role in the cognitive structure of interactants, has led

me to develop the notion of 'discourse grammaticalization' (Romero Trillo, 2001). According to this view, discourse markers are elements that have undergone a process of discourse grammaticalization and have included in their semantic/grammatical meaning a pragmatic dimension that has interactional purposes. In other words, a grammaticalized marker becomes a homonym in a particular synchronic system that, when realizing a discourse function, constrains the relevance of the proposition it introduces, as Hopper and Traugott (1993) have suggested.

Based on the work on grammaticalization by Heine *et al.* (1991) and Hopper and Traugott (1993), I have classified discourse markers as follows (Romero Trillo, 2001):

- Acategorical items such as: *yeah*, *yep*, *m*, *mhm*, *etc.*
- Lexical items such as: *listen*, *well*, *good*, *fine*, *etc.*
- Lexical composites such as: *I mean*, *you know*, *the thing is*, *oh my God*.

The discourse grammaticalization approach to discourse markers – an approach shared by other scholars such as Aijmer (2002) – addresses the question of the versatility of meanings and the nontransparent nature of these elements that may not have a unique pragmatic meaning.

The problem now is: how can we account for the alternative options that we have, for example, for showing feedback in a certain situation in a particular language? Clearly, several elements (*I see*, *I know*, *yes*, *yeah*, *m*, *mhm*, *aha*, *etc.*, ...) could realize such a function. The only possible way out of this quandary is by appealing to the notion of appropriateness, defined as "the possibility to choose the most adequate element in the realization of a certain function in a specific context" (Romero Trillo, 2001: 531). By using the notion of appropriateness, I emphasize that the use of a particular form in discourse is not dependent on any kind of grammatical assessment (as a matter of fact, many discourse markers do not belong to any particular grammatical category, as I mentioned above), but on the frequency with which it appears in a significant corpus-based language sample (representing a native speaker's linguistic competence).

Appropriateness is based on the assumption that there are no preestablished rules that determine the correct or incorrect use of a given element as a discourse marker, but that speakers will rely on the regularities of certain parameters that are considered adequate to a given linguistic situation. These parameters are not only linguistic but also extralinguistic, such as social class, context of the situation, age of the speakers, etc. (see **Class Language; Context, Communicative**).

Another interesting feature of discourse markers is their autonomy in the development of a second language. In other words, teachers and learners of a language tend to concentrate on the acquisition of the grammatical and lexical elements that enable communication, but tend to disregard the study and development of the pragmatic weight that discourse markers add to language learning. In fact, several studies show that the pragmatic component of language learning that is formed by cognitive, affective, and linguistic elements (discourse markers) is difficult to reproduce in the nonnative language teaching class (Romero Trillo, 2002). This is the reason why nonnative speakers suffer from what I call 'pragmatic fossilization,' as it is especially evidenced in the use of discourse markers (Romero Trillo, 1997, 2002); that is to say, the evolution of the learners' interlanguage does not include a development in the use of discourse markers similar to the native-language speakers as to frequency and diversity. In my study of the evolution of discourse markers, I made the general distinction between 'operative markers' (those dealing with managing concepts or tools), and 'involvement markers' (those dealing with social rapport). This comparative study showed that there is a similarity in the use of operative and involvement markers at an early age in native and nonnative children. However, with learners' increasing age, involvement markers become difficult to acquire for nonnatives, a fact that leads to a pragmatic fossilization in their use of such markers (i.e., nonnative speakers tend to use the markers that they acquired when they were children). This fossilization is more evident when the native and the target language realize a certain function with divergent translational equivalent markers (see Romero Trillo (1997) on the use of attention-getting markers in Spanish and English). In fact, the fossilization of discourse markers reveals the shortcomings of learning a foreign language in a nonnatural environment, especially as to the use of the elements that contribute to the pragmatics of interaction.

Discourse Processing

M Gernsbacher, University of Wisconsin, Madison, WI, USA

M Kaschak, Florida State University, Tallahassee, FL, USA

© 2006 Elsevier Ltd. All rights reserved.

In our daily lives, we are often asked to comprehend language in units larger than the single sentence. For example, when we follow instructions for how to set the clock on our VCR, we need to develop our understanding of the situation over the course of several sentences (e.g., “Wait until you see the red light flashing. Then, hold down the ‘Time’ button and...”). When we have a conversation, the meaning of a particular utterance may be based on our understanding of previous utterances (e.g., the meaning of ‘him’ in the sentence “Ask him where the briefcase is” depends on our understanding of the referent’s previous mention). When we read or listen to stories, the narrative is built up across many sentences, paragraphs, and typically chapters. The preceding examples of language use are examples of discourse, and discourse processing is the processing involved in building meaning across several sentences or utterances. Although research on discourse processing has grown to encompass work done in a range of fields (e.g., linguistics and education), the focus of this article will be research that has grown out of the field of psycholinguistics. We begin by discussing the research paradigms most widely used to explore issues in discourse processing. Then, we outline several of the major theories of discourse processing. We conclude by reviewing several domains in which discourse processing has been explored.

Methods of Studying Discourse Processing

Over the past several decades, discourse-processing research has focused on the comprehension mechanisms that operate while readers comprehend a text or listeners understand a conversation – as it unfolds. The methods used in this pursuit have been a mixture of both on-line and off-line measures. On-line measures are often timing-based measures designed to assess the moment-by-moment operation of the language comprehension system. Off-line measures are typically based on responses such as paraphrases and answers to comprehension questions; such measures are not necessarily intended to directly tap the moment-by-moment operation of the comprehension system.

On-Line Paradigms

There are two major methodological paradigms that are based principally on on-line measures: the inconsistency detection paradigm and the probe response paradigm. These paradigms use reading times, lexical decision times, and naming times (among other measures) as primary dependent measures.

Inconsistency Detection The inconsistency detection paradigm was introduced by O’Brien and Albrecht (1992). Participants are asked to read a passage such as the following:

Jane woke up on Thursday morning in a panic. Her rent check was due the next day, but there was no money in her bank account. When she walked into the kitchen, she remembered that she hadn’t yet deposited the large refund check that she had gotten from the IRS. After getting dressed, **she grabbed the check and drove to the beach.**

The narrative begins with a sentence or two designed to introduce a fact about (or a goal for) the main character. In this case, Jane needs to get some money into her bank account. At the end of the narrative, there is a critical sentence (or clause) that conflicts with information presented earlier in the passage. In the example narrative, the bold clause at the end of the passage is the critical one: if Jane needed to get the check to the bank, readers should find it strange that she took the check to the beach. If readers notice this inconsistency, they should have difficulty understanding the critical sentence. The comprehension difficulty slows the readers down, such that they read the critical sentence more slowly than a version of the same sentence that is consistent with the information presented at the beginning of the narrative (e.g., “After getting dressed, she grabbed the check and drove to the bank”).

The inconsistency detection paradigm has been used to explore several issues in discourse processing. For example, the paradigm provides a means of assessing what information readers remember as they work their way through a narrative. If their reading times slow down for a sentence that is inconsistent with information provided earlier in the narrative, their slowed reading times suggest that they remember the previously presented information. The inconsistency detection paradigm has also been used to investigate how readers draw inferences during discourse processing. Sometimes the inconsistent information is inconsistent only with implicit rather than explicit information.

Probe Response The second major paradigm that has been used in studies of discourse processing is

the probe response task. Participants are asked to listen to or read passages such as the example presented above, and at some point during the passage the participants are presented with a probe word (i.e., a word that may or may not be related to the theme of the narrative). For example, at the end of the 'rent check' passage presented above, participants might see the probe word 'bank.' In one version of the probe response methodology, participants are asked to make a lexical decision on the probe word. That is, they are asked to judge whether the probe is a real word or not ('nust' is an example of a nonword). If the concept named by the probe word (bank) is currently active in the comprehender's representation, they should respond to the probe word faster than they would respond to a probe word that is unrelated to the narrative (e.g., 'bird' is a word that is unrelated to the 'Jane' passage). If the concept named by the probe word is not currently active, it should not be responded to faster than an unrelated probe word. Other versions of the probe response paradigm use naming tasks as the primary dependent measure (i.e., participants are shown a probe word and required to pronounce aloud the word as rapidly as possible).

The probe response methodology has been used to study a wide range of topics in discourse processing. Variants of this task have been employed to assess when comprehenders draw inferences while processing narratives, the nature of the inferences drawn, the way that certain elements of a discourse remain active in memory (or not) as more of the discourse is processed, how comprehenders keep track of the characteristics and goals of the protagonists in a discourse narrative, and many other issues.

Off-Line Methods

Several kinds of off-line measures have been employed to understand the comprehension of discourse. Paraphrase tasks, in which participants are asked to paraphrase what they have heard or read, have been used to study what comprehenders remember about various aspects of a discourse (e.g., how much of the surface form do they remember? how many of the details do they remember?) and what inferences they have drawn. Another off-line measure that has been used is the question-answering task. Participants' answers to comprehension questions are used to assess the representations that comprehenders generated for a discourse. Think-aloud paradigms, in which participants are asked to think aloud about their developing understanding of a discourse, have been used to explore the comprehension strategies employed as comprehenders work their way

through a discourse. Whereas there is some question about the extent to which these off-line measures provide a true reflection of the processing mechanisms that operate during, rather than after, comprehension, measures such as those listed above provide valuable information about the representations that are constructed from a discourse.

The Three-Pronged Approach

Arthur C. Graesser and colleagues (see Graesser *et al.*, 1997) have advocated a three-pronged approach to the study of discourse processing. This approach is a combination of on-line and off-line measures. The three prongs of this approach are (1) developing hypotheses from theories of discourse processing, (2) employing off-line measures to obtain a detailed understanding of the strategies used during discourse processing, including an understanding of the inferences drawn and constructs and elements best remembered, and (3) on-line measures to determine how these inferences and strategies are employed by the comprehension system to build a representation of the discourse in real time.

Theoretical Approaches to Discourse Processing

Several theories of discourse processing have been proposed over the past two decades. These theories differ in the cognitive mechanisms that are evoked to explain how discourse is understood, but they agree on several issues:

1. Comprehension of a discourse leads to a mental representation of that discourse.
2. Comprehenders routinely update their mental representations. Updating involves the integration of new information into their existing representation of the discourse.
3. Comprehenders draw at least some inferences during the comprehension of discourse. These inferences help to maintain discourse coherence at both global and local levels.
4. Some of the information from the discourse remains highly active in memory (i.e., in the foreground of the discourse), whereas other information is less active in memory (i.e., in the background of the discourse). Whether a given element is in the foreground or the background of the discourse depends on the current focus of the discourse.
5. The comprehension of a discourse can be affected by a number of variables, such as the genre of the discourse being processed and the comprehender's goals for understanding the discourse.

These themes of discourse-processing research have been integrated into and explained by a number of individual theories.

Construction-Integration Model The construction-integration model was proposed by Kintsch (1988). This model proposes that discourse is comprehended in two iterative stages. In the construction stage, the incoming text base, which is a representation of the content of the discourse but not of the actual words and phrases in the text) enters working memory; in working memory, the text base retrieves potentially relevant information from long-term memory. This stage of processing can be described as ballistic: it happens quickly and automatically. During the integration stage, the comprehension system begins to integrate the new information with the previously existing model of the discourse. The integration stage is comparatively slow and resource consuming, as the comprehension system pares down the information activated in the construction stage and integrates only the information that is most relevant to the present situation into the model of the discourse. The resulting representation is called a 'situation model.'

Structure-Building Framework The structure-building framework was outlined by Gernsbacher (1990). The theory proposes that discourse comprehension proceeds by building mental representations of the information presented in the discourse, with the initial process in building a structure called 'laying a foundation.' The foundation of the structure is based around the characters and events initially presented in the discourse. When new information is presented, it can either be mapped to the existing structure (i.e., it is attached to the existing structure), or it can prompt the comprehension system to shift to a new structure (i.e., the comprehender lays the foundation for a new structure). Finally, some information in the structure can be enhanced, made more available for further processing, whereas other information can be suppressed, made temporarily unavailable for further processing.

Event-Indexing Model The event-indexing model was discussed in Zwaan *et al.* (1995). It proposes that comprehenders continually monitor the discourse model to maintain coherence on five dimensions: protagonist (who is involved in the events being described?), time (at what time is the event taking place?), space (what are the spatial relations between the characters, objects, and events being described?), causality (are the events in the discourse causally related to each other?), and intentionality (is the

incoming information relevant to the protagonist's goals and intentions?). Shifts on any one of those dimensions (e.g., if the discourse indicates some temporal delay between one event and the next) are typically associated with some processing cost as comprehenders update their representation. The largest processing costs tend to be associated with discontinuities on the time and protagonist dimensions.

Memory-Based Approach Myers and O'Brien (1998) described the memory-based approach to discourse processing. Whereas other models might posit the operation of 'active' processing mechanisms (in the sense that these mechanisms actively retrieve information when building a representation of the discourse), the memory-based approach is built on passive mechanisms of memory retrieval. The memory-based approach is based on Hintzman's (1986) MINERVA, and its 'resonance' process of memory retrieval. On this view, incoming information resonates both with the existing model of the discourse and with information in long-term memory. Information from memory is used to interpret the incoming sentence to the extent that it resonates with the new information.

For a more detailed review of these and other models of discourse processing, the reader is directed to Britton and Graesser (1996).

Theoretical and Empirical Issues

The final section of this article reviews a set of findings that bear on those aspects of discourse processing that have been most widely studied.

Integrating Sentences into a Coherent Discourse

One of the most basic questions in discourse-processing research is how comprehenders connect a series of utterances or sentences into a coherent whole. This issue can be separated into a series of smaller questions. First, how does the comprehender know that a series of utterances or sentences are intended to be interpreted as a connected discourse? There are several linguistic cues that signal the coherence of a discourse. David A. Robertson and colleagues asked comprehenders to process a series of sentences such as "The family rode together in a car" (Robertson *et al.*, 2000). When the series of sentences began with the definite article, comprehenders tended to interpret the series of sentences as part of a connected discourse. On the other hand, when the same sentences were presented with the indefinite article, comprehenders tended to interpret the sentences as being unrelated to each other. Thus, cues as subtle as the articles that are used in subsequent sentences

indicate whether those sentences should be interpreted as related or not. Connectives such as *because*, *however*, *meanwhile*, and others play a similar role. For example, in the sentences “The mother was preparing food for the party. Meanwhile, the grandparents were loading the minivan,” although the focus of the two sentences is different, the connective *meanwhile* indicates to comprehenders that both sentences should be interpreted as part of the same discourse model.

Once comprehenders have begun to integrate a series of sentences into their mental representation of a discourse, they must continue to process each subsequent sentence. There are several strategies that might be used. Comprehenders might connect each incoming sentence to the most recently encountered sentence. In doing so, the comprehender is attempting to maintain local coherence (see, e.g., McKoon and Ratcliff, 1992) in their discourse model. On the other hand, comprehenders may attempt to maintain global coherence in their discourse model (see, e.g., Graesser *et al.*, 1994; Singer *et al.*, 1994). That is, comprehenders might connect each incoming sentence by virtue of the overarching themes of the discourse (e.g., the goals of the protagonist).

In general, comprehenders attempt to maintain both local and global coherence. Experiments using the inconsistency detection paradigm discussed above demonstrate the guidance afforded by global coherence. For example, if a narrative begins by presenting a goal for Jane (she needs to get money into her bank account), and several sentences later, the comprehender is told that Jane is going to the beach without meeting her goal, comprehension will typically slow down. The slowed comprehension suggests that the overarching goal – a component of global coherence – affects processing individual sentences (see, e.g., Albrecht and O’Brien, 1993). Additionally, it is clear that comprehenders attempt to maintain local coherence from sentence to sentence (see, e.g., McKoon and Ratcliff, 1992). If a given discourse has too little local coherence, it will be viewed as altogether incoherent.

Comprehenders pay attention to several elements of the discourse in attempting to maintain coherence. Chief among them are space (where are the events taking place?), time (when are the events taking place?), the protagonists being described, causality (is there a causal relationship between the events being described?), and the goals of the characters (Zwaan *et al.*, 1995). An incoming sentence can potentially violate coherence on these (or other) dimensions. The more dimensions that are violated by the incoming sentence, the more difficult that sentence will be to understand and to integrate into the existing representation of the discourse.

There is a considerable amount of evidence in support of the claim that these dimensions are important for maintaining the coherence of a discourse. Space has been shown to be important in several ways. First, when two objects are described as being in different locations, focusing the discourse on one of those objects makes the other less accessible to the comprehender (see, e.g., Glenberg *et al.*, 1987). Second, in studies in which participants study the layout of a building before reading a narrative about events that take place in that building, reading times are sensitive to the relative distances between the rooms in the building. Sentences that describe a character moving between adjacent rooms of the building are read more quickly than those that describe a character moving between nonadjacent rooms (see, e.g., Morrow *et al.*, 1987).

Time is less well studied than space (i.e., the spatial dimension) but has an equally strong effect on language processing. Zwaan (1996) asked participants to read passages which contained a shift in temporal perspective. The time shift was either small (“A moment later. . .”) or large (“A day later. . .”). Comprehenders took more time to read sentences with a large temporal shift than to read sentences with a small temporal shift. Subsequent experiments have provided more support for claims about the importance of the temporal dimension (Rinck *et al.*, 2001).

The remaining elements outlined above – protagonist, causality, and intentionality – have received less attention than space or time. The research that does exist on these topics is generally supportive of the claim that shifts on any of these dimensions can lead to processing difficulty. A more detailed understanding of how each of these dimensions works, and how the dimensions are used together during discourse comprehension, is needed.

Generating Inferences during Discourse Processing

To achieve successful comprehension, the comprehender must often fill in details that are not explicitly presented in the discourse. That is, the comprehender must generate inferences about the events being described in order to maintain a coherent representation of the discourse. For example, when they encounter a pair of sentences such as “It was very cold that winter morning. Joe slipped on the sidewalk,” comprehenders need to draw the inference that there may have been snow or ice on the sidewalk in order to integrate the two statements into a coherent discourse model. The processes through which inferences are generated have been explored extensively over the past two decades.

One of the major research questions about inference generation during discourse processing has centered upon the issue of when inferences are generated and when they are not. According to the minimalist position (McKoon and Ratcliff, 1992), comprehenders mostly attempt to maintain local coherence when they process a discourse. The only inferences that are routinely generated by comprehenders are those that are required to maintain local coherence (such as the inference that there was ice on the sidewalk from the example in the previous paragraph). Comprehenders are capable of drawing more global inferences from discourse, but these inferences are only drawn under certain circumstances (e.g., when the comprehender is attempting to process the discourse more deeply than usual). In contrast, the promiscuous position maintains that comprehenders routinely generate a wide range of inferences from the discourse, including those that are not strictly necessary to ensure local coherence. These inferences include inferences about the goals of the characters, the emotional state of the characters, the cause-and-effect relationship between events in the discourse, the intent of the writer in conveying particular pieces of information, and so on.

A compromise between these extreme positions is the constructivist position. The constructivist position holds that comprehenders routinely draw inferences that meet their goals as comprehenders, inferences that maintain the coherence of the discourse, and inferences that explain why different events in the discourse are taking place. On this view, comprehenders may appear to behave in accord with the minimalist position under certain conditions and in accord with the promiscuous generation position under other conditions, depending on the nature of the discourse and the goals they have in comprehending that discourse. For example, if the comprehender is attempting to skim the discourse in an effort to quickly glean information, they may draw few inferences (in keeping with the minimalist position). On the other hand, if individuals are reading a discourse for enjoyment (say, if they are reading a detective novel) or if they are trying to learn about a new field of study, they may read the discourse more carefully and draw a wider range of inferences.

Another topic of import with regard to inference generation during discourse processing is the mechanism(s) through which the inferences are drawn. It is undoubtedly the case that many kinds of inferences (especially those relating to the local coherence of the discourse) are drawn by combining information from the incoming discourse with 'world knowledge' retrieved from long-term memory. For instance, when we read that it is cold outside, we can infer that it is

probably wintertime. When we read that the character in the discourse has slipped on the sidewalk, the knowledge that snow and ice can be on the sidewalk during the winter is retrieved from memory, supporting the inference that the snow or ice has caused the character to fall. This sort of inference generation can be explained via the mechanisms of many of the theories outlined earlier. For example, the construction-integration model proposes that inference generation is supported by the rapid, automatic retrieval of world knowledge during the construction stage of comprehension. On the other hand, much less is known about how more global inferences (e.g., inferences about the goals of the characters, the purpose of the author in writing the discourse, and the theme of the discourse) are generated. It seems likely that world knowledge of the sort described above contributes to the generation of these global inferences. Additionally, metalinguistic knowledge about different genres of discourse (e.g., that newspapers are supposed to be balanced and factual, that detective stories should build suspense) may also help the comprehender to draw inferences about the purpose and structure of the discourse.

Determining Reference in Discourse Processing

When discourses are produced, they do not repeatedly use the same word to refer to a particular object or person. A character may be introduced as 'Jane,' and in the next sentence be referred to as 'she,' and later in the discourse be referred to as 'the woman with the brown hair.' In order to maintain the coherence of the discourse, the comprehender must realize that 'Jane,' 'she,' and 'the woman with the brown hair' all refer to the same person.

The most well-studied case of reference in discourse processing is the comprehension of anaphoric reference, or reference to a person or object that has previously been mentioned (as in the above example). One factor that influences the comprehension of anaphoric references is the nature of the information currently active in memory (and foregrounded in the discourse). If there is one female character currently in the foreground of the model (Jane), then pronouns such as 'she' will be mapped onto Jane. If there is more than one female character in the foreground of the model, the pronoun will be mapped to the one whose representation is most active. In some cases, further knowledge is needed in order to determine the referent of an anaphor. When Jane is referred to as 'the woman with brown hair,' the comprehender needs to know that Jane has brown hair in order to easily understand the reference as intended.

The choice of reference for an entity in the discourse depends largely on the circumstances in

which the entity is being mentioned. When a person or object is initially mentioned, it is usually marked with the article *a* or *an*, and the description provided is typically somewhat detailed. Subsequent references are less detailed, and may be made by pronouns or other 'shorthand' referring expressions. The more the entity has been mentioned in the discourse, the shorter the referring terms tend to be. The change in referring terms is related to the given/new distinction in language use. Information that is given (i.e., that is already established in the discourse) may be referred to in a shorthand manner because it is assumed that the comprehender already knows what is being talked about. Information that is new (i.e., information that is assumed to be unknown to the comprehender) is described in more detail to ensure that the comprehender has the relevant information to process subsequent discourse.

Conclusion

This article has presented a brief overview of the literature on discourse processing. We have discussed the overarching themes of this work, the major theories of discourse processing, and the subareas of discourse processing that have received the most attention in the literature. Nonetheless, our review has not done justice to the ways in which perspectives on discourse processing have been used in fields such as education, linguistics, communications, and communication disorders. Without a doubt, the field of discourse processing will continue to grow and flourish as researchers attempt to understand the complexity of the processing involved as comprehenders understand discourse.

Discourse, Foucauldian Approach

A McHoul, Murdoch University, Murdoch, Australia

© 2006 Elsevier Ltd. All rights reserved.

There exists today a problem which is not without importance for political practice: the problem of the status, of the conditions of existence, of functioning, of the institutionalizing of scientific discourses. That's what I have undertaken to analyze historically – by choosing the discourses which have, not the strongest epistemological structure (mathematics or physics), but the densest and most complex field of positivity (medicine, economics, the human sciences). (Foucault, 1978: 20)

I am not just amusing myself by making the game more complicated for a few lively minds. I am trying to define in what way, to what extent, to what level discourses, and particularly scientific discourses, can be objects of a political practice, and in what system of dependency they can be in relation to it. (Foucault, 1978: 23)

This article looks at the relatively early works of Michel Foucault, especially *The order of things* (1970) and *The archaeology of knowledge* (1972). These are the two major works that stem from a time when Foucault was critically interested in the concept of discourse and how it might be taken out of its hitherto (very broadly) 'linguistic' context and reconnected with his own discipline, which he called the history of systems of thought. The article is more or less confined, then, to that period of his thinking, though with some excursions into the so-called 'middle period' when Foucault's main concern centered more around the idea of power. By this later time, the concept of discourse had all but disappeared from the surface of Foucault's writings, to be displaced by the concept of apparatus (*dispositif*) and, at a later stage, by the idea of technologies of the self (cf. Hunter, 1991).

Among critical discourse theorists such as Foucault, the term 'discourse' refers not to language or social interaction as formal systems or as matters for empirical analysis but to relatively well-bounded areas of historically specific knowledge that determine what a human subject can possibly be or become at a given time. That is, it is deeply connected with what might be called the politics of the self and identity, and with exceptions, it is almost impossible to find this use of the term in other – largely Anglo-American – approaches to discourse. (One exception is, of course, the approach called New Historicism, and Foucault himself makes acknowledgment of this in his preface to *The use of pleasure* [1986].) If our prior conceptions of discourse have been mainly linguistic or quasisociological ones, to understand Foucault's approach, we may now have to completely

rethink the idea. We may even need to be prepared to think of it as a totally different concept in a totally different field that just happens to have the same name as something we already know and take for granted as discourse analysts. (Though, for a recuperation of Foucault into linguistically based forms of discourse analysis, see Fairclough [1989].)

According to this approach, in any given historical period we can write, speak, or think about a given social object, practice, or positioning – madness, for example, or gender – only in certain specific ways and not others. (On madness, see Foucault (1967), and on gender, see Sawicki (1991).) The overall point is that discursive categories such as, say, 'schizophrenic' or 'homosexual,' are historically distinct ways of thinking about ourselves and others. They cannot be presumed to have existed 'essentially' throughout time and space.

'A discourse' would then be whatever constrains – but also enables – writing, speaking, and thinking within such definite historical limits, and we must deliberately refer to 'a discourse' or 'discourses' in the count-noun form, for even though Foucault frequently uses the mass noun 'discourse,' he is typically keen to point out that this is something of a theoretician's shorthand, a way of signaling some common and general properties of particular discourses. Historically specific discourses (e.g., medicine and proto-psychology in the nineteenth century) are quite distinct from one another as well as from earlier and later forms of 'themselves' that may or may not have the same names.

However, these discourses can also overlap and intersect as they change historically, such as those discourses on life, labor, and language we call biomedicine, economics, and linguistics. Foucault tried to trace these complex comings together and departures in *The order of things* (1970). Sometimes he treats the discourses separately; at other times he looks at their contribution to the possibility of each period having an overall view of the world (which he calls the Western episteme). For example, he finds that, in the 16th century, the 'table' of the human sciences had no concepts of life and labor at all. Nor was language thought of as a signifying system or 'medium': it was simply there as "one of the figurations of the world" (1970: 56), a naturally useable substance like air or water. Moreover – and this may be difficult for contemporary readers to appreciate – there was no concept of 'man' or 'humanity' at this time. In fact, Foucault argues that what we now call 'humanity' had no way of conceptualizing its separateness until the 19th century. 'Man,' in this

account, is barely a couple of centuries old. Before this, there were different connections and separations to be made.

We should note here that *The order of things* is clearly dependent, in many respects, on Martin Heidegger's deep suspicions concerning the historical fragility of the concept of 'man' – though Foucault's work makes no direct acknowledgment to any such source. This may be because Heidegger's own dating of 'man' has the concept arrive much earlier than does Foucault's (for details, see Heidegger, 1997).

To take an example from before the centrality of the idea of 'man,' the discipline called 'natural history' in the 17th and 18th centuries was purely descriptive and taxonomic. It dealt with tables of types; in this case, tables of life-forms. Natural historians merely collected, described, and tabulated species and types; they never tried to form overall theories of life in general (as did, e.g., Darwin in the 19th century). Such forms of thought simply were not available, and the same was true of the discourse concerning labor in these earlier times. The discipline then known as the 'analysis of wealth' merely tried to examine forms of exchange and trade, as though what we would now think of as humanly produced ('man-made') commodities were 'natural' things to be bought and sold. There was also, at this time, a discourse that dealt with language called 'general grammar.' Just as natural history collected and tabulated species, and the analysis of wealth categorized forms of exchange, however, so did general grammar seem happy to separate language into, for example, nouns and verbs and to create taxonomies of their types.

By the early 19th century, however, these three discourses had become much more distinct. They had become separate sciences: early biology (whose major figure is Cuvier), early economics (Ricardo), and philological linguistics (Bopp). As the period known as the Enlightenment (Rabinow, 1987: 32–50) – and particularly Kant's analysis of the limits or finiteness of what knowledge could achieve – began to have its belated effect beyond philosophy proper, these separate discourses appeared to have a previously unforeseen object in common: 'man' as both the one who was able to 'know' and, simultaneously, as the area or object to which knowledge should primarily be applied. (Again, this version of 'man' in Foucault is highly dependent on Heidegger's [1997] analysis of the emergence of 'man' as *subjectum* in/as the earliest moments of modernity.) It only then became possible to say, think, or write that man lives, man labors, and man speaks. This makes possible the field of the human sciences as Foucault knew it in his day, so that there emerged new objects requiring new

analyses, with distinct discourses covering each of the three areas: psychology (human life), sociology/economics (human labor), and literature and myth (human signification, as it were, 'man' to 'man').

Then, in the 20th century, structuralism announces the supposed 'death of man,' the idea that this seemingly old, but actually quite recent, conception of man is a fiction and has always been 'really' absent, and that what we strangely confine to the category of 'humanity' is a highly delimited conception of being. With respect to 'life,' psychology is (we hear) replaced by psychoanalysis, which assumes that a uniform structure known as 'the unconscious' inhabits each of us in more or less identical ways. (The unmarked figure is Lacan.) As for 'labor,' ethnology now replaces general sociology/economics, and structural conditions situate human societies as mere responses (albeit differentiated) to universal conditions and needs (Lévi-Strauss, perhaps?). In the case of 'language,' structural linguistics looks for universals beneath the specific, local, and unique bits of language that are actually written and spoken (Chomsky?). At this point, contemporary discourses (including, we might add, the discourses on discourse itself) are put in their historical position. They are pluralized so that they no longer seem to have unique access to fundamental truths. Truth becomes a function of what can be said, written, or thought, and Foucault's (1981: 6) poststructuralist project becomes one of exposing the historical specificity – the sheer fact that things could have been otherwise – of what we seemed to know during Foucault's own 'today' (i.e., c. 1970) with such certainty.

Our more immediate question is, after all, what does Foucault mean by 'discourse'? After working on what he called the discourses of life, labor, and language in *The order of things*, Foucault (1972) immediately began to try to theorize the concept of discourse as such in his next book, *The archaeology of knowledge*. This is perhaps Foucault's most difficult work. *The order of things* is complex enough as it is, but to trying to read a complicated theoretical reflection on it (which is what *The archaeology of knowledge* is) in the absence of *The order of things* is a near impossibility. Still, *The archaeology of knowledge* is the main work in which Foucault tries to spell out what he means by 'discourse.' The best way to deal with Foucault's approach to discourse, however, is to work carefully through *The order of things* (despite its seemingly arcane history of the human sciences) and then to read *The archaeology of knowledge* for a more theoretical formulation of Foucault's rethinking of this topic.

Because the type of 'discourse theory' to which Foucault contributed is less well known in

English-speaking circles than are formal and empirical approaches, a brief historical preamble is in order. Pre-Foucauldian critical discourse theory originated in continental, largely French, philosophical traditions. It had its most cogent application in relation to the history of ideas rather than to the analysis of either formal language systems or social structures. O'Sullivan *et al.* (1983: 72–73) argue that it began with structuralism itself and its opposition to those “inherited habits of thought and analysis” which assumed that social and cultural ‘objects’ existed in the ‘real world’ ready to be seized or (as one said in those days) ‘adequated.’ The structuralists, particularly the early Roland Barthes, tried to show that, on the contrary, these objects exist only “as *products*, not *sources*, of ... signification.” But this position on discourse – which still differs from Foucault’s in that it attaches discourse primarily to signification – did not mean that ‘anything goes.’ Because ‘objects’ are said to be ‘discursively produced,’ this does not imply that we can make the world into anything we want simply by speaking, writing, or thinking in a certain way (Macdonell, 1986). Instead, structuralist and semiotic approaches to discourse were intended as critiques of individualism and idealism. According to this position, what we can imagine (let alone put into practice) is both permitted and constrained by the structurally available discursive possibilities at our disposal.

Foucault, however, argues that both formal and empirical approaches to discourse have tended to work on the side of the enunciation (*énonciation*) of discourse. By ‘enunciation,’ he means the techniques, the structures, the forms of know-how by which people are able to produce and recognize utterances. Such a narrow focus can include only the surface of language use, the ways and means by which concepts and meanings are spoken or written. In place of this emphasis, Foucault (1972) proposes to look at discourses (again in the plural) – historically specific bodies of knowledge – at the level of the enounced (*énoncé*) or, as his translators have it, the ‘statement.’ This change of emphasis moves discourse away from being simply a technical accomplishment (linguistic or interactional) on the part of preexisting subjects and redirects it toward the questions: What can possibly be said? And what can possibly be thought? Ergo: What can a subject be?

Referring back to his historical analyses in *The order of things*, Foucault (1972: 80) considers his failure there to specify the terms ‘discourse’ and ‘statement’ (*énoncé*):

Instead of gradually reducing the rather fluctuating meaning of the word ‘discourse,’ I believe that I have in

fact added to its meanings: treating it sometimes as the general domain of all statements, sometimes as an individualizable group of statements, and sometimes as a regulated practice that accounts for a certain number of statements; and have I not allowed this same word ‘discourse,’ which should have served as a boundary around the term ‘statement,’ to vary as I shifted my analysis or its point of application, as the statement itself faded from view? (Foucault, 1972: 80)

To clear up this confusion, Foucault asks whether we could think of the statement as a unit of (a) discourse, just as the sentence is a unit of (a) language. If so, it is then necessary to ask what kind of unit it is. For example, would it be exactly the same as a proposition, a sentence, or a speech act? Let us take these in order.

First, a statement cannot be the same as a proposition. The proposition is the basic unit of logical analysis: a declarative utterance describing an actual state of affairs, or else a ‘truism.’ Taking Foucault’s (1972: 81) own example, the propositions “No one heard” and “It is true that no one heard” have identical propositional ‘contents’ – to all intents and purposes they are the same proposition. But they may constitute two different statements. We can see this by asking what they state in particular circumstances. If each were to occur as the first line of a novel, for example, Foucault (1972: 81) continues, they could provide the scene-setting for quite different kinds of narrative. The first – “No one heard” – could be “an observation made either by the author, or by a character,” whereas the second “can only be in a group of statements constituting an interior monologue, a silent discussion with oneself, or a fragment of dialogue, a group of questions or answers”.

According to this theory, Foucault’s first criterion for a statement is that it should be responsive to what Pêcheux (1975) calls ‘functioning.’ Propositional content, at least in traditional logic, is thought to remain constant across different local usages. But unlike propositions, statements – as components of discursive formations – have to be thought of primarily as functional units. They do things, bring about pragmatic effects, rather than merely ‘represent’ states of affairs.

Second, Foucault argues, a statement is not the same as a sentence, at least as far as we can tell. Truncated ‘sentences’ – such as ‘Absolutely!’ – can, it is true, carry the force of statements. They can do things and create pragmatic effects, but this objection is trivial. Even formalist approaches acknowledge that such truncations can count as sentences. In fact, the sentence (according to any of the various schools of linguistics) is itself very difficult to define, and so we will never be in a position to decide clearly one

way or another about the correspondence (or lack of it) between sentences and Foucault's statements. However, there is some relatively firm ground, for it is possible to say that certain word groupings that are clearly not sentences do carry the force of statements. Foucault's (1972: 82) example is the paradigm of the Latin verb *amare* – *amo*, *amas*, *amat* ... – which schoolchildren once had to recite in class. Obviously, and perhaps even by definition, this is not a sentence, for it lists the forms that can 'fill slots' (verb positions) in actual Latin sentences. Yet it is still a statement, a "statement of the different personal inflections of the ... verb." Thus, classificatory schemata, tables, maps, and taxonomies, though rarely expressed as sentences, can be statements. The periodic table of the elements is a statement, and so is a price schedule or a timetable.

More importantly, these examples show clearly how groups of statements (where 'groups of statements' is approximately equal to 'discourses') act to both constrain and enable what we can know. Statements, that is, cannot be characterized by their syntactic or grammatical forms. Expressions that do not use verbal language can be statements: "a graph, a growth curve, an age pyramid, a distribution cloud" (1972: 82). The important thing (and this is Foucault's second criterion for a statement) is that statements should be component parts of knowledge systems ('systems of thought').

Third, a statement cannot be the same as a speech act. Austin (1975) argued that speech acts (e.g., saying "I do" during a wedding ceremony – a performative utterance that accomplishes an event in and by its very saying), to be successful, must meet certain 'felicity conditions.' Not all instances of "I do" will count: it must be said in front of someone who is vested with the authority to conduct marriages, the two parties must consent, and so on. It is true that both Austin's speech acts and Foucault's statements can be said to 'accomplish' events and create effects, but equivalences between (some) speech acts and (some) statements are merely coincidental.

Can we say, for instance, that there is equivalence between "I promise" when it is said as a proposal of marriage within the discourse of medieval romance and "I promise" when it is said as an agreement to meet for lunch? Perhaps these are equivalent speech acts (strictly, they are both 'commissives'), but each is a different statement. The two statements occur in totally different social 'technologies' and historically formed discursive practices. Each, if successful, produces distinct kinds of human subjects: lovers and lunchers; each, again if successful, (re)creates and maintains political institutions as different as love and lunch. Hence the third criterion for

a statement is that it should be part of a technique or techniques for the production of human subjects and institutions.

Returning to Foucault's initial question about whether statements are perhaps 'units' of discourses, we can see that the answer is a qualified 'no.' A statement is not strictly a unit at all in the way that the proposition, the sentence, and the speech act may be. Instead, it is a "function that operates vertically in relation to these various units, and which enables one to say of a series of signs whether or not they are present in it" (Foucault, 1972: 86). It is "not itself a unit, but a function that cuts across a domain of structures and possible unities, and which reveals them, with concrete contents, in time and space" (1972: 87). Statements can therefore be understood not as fixed components, but only via the rules that govern their functioning. However, these rules are not like, for example, grammatical rules: They have to do with historically variable bodies of knowledge, they are the rules for what it is possible to know. Hence, they are not susceptible to (nor can they help us arrive at) a general theory of language.

Statements and the rules that govern them are not purely linguistic (indeed, we have seen that they can be completely nonlinguistic), nor are they purely material, but in fact, they connect these two domains. To analyze or describe discursive rules, in Foucault's sense, we must always turn to specific historical conditions – to the piecemeal, the local, and the contingent. Events, no matter how specific, cannot happen just anyhow. They must happen according to certain constraints, rules, or conditions of possibility. These restrictions mean that discourses always function in relation to power relations in Foucault's rather idiosyncratic sense of the term. Because power is crucial to any understanding of Foucault's theory of discourse, we must consider it here briefly, if prematurely.

For Foucault, 'power' is very different from traditional sociopolitical conceptions of it. Discourse is not a mere effect or end-product of preexisting Power (with a capital 'P'). Nor is power 'owned' by some privileged person or group and exercised "simply as an obligation or a prohibition on those who 'do not have it'" (Foucault, 1977: 27). Power, for Foucault, is not just the ruthless domination of the weaker by the stronger (to paraphrase Nietzsche); in fact, it is not to be 'had' at all.

Power is everywhere; not because it embraces everything but because it comes from everywhere ... Power comes from below; that is there is no binary and all-encompassing opposition between ruler and ruled at the root of power relations, and serving as a general matrix – no such duality extending from the top down and reacting on more and more limited groups to the

very depths of the social body. One must suppose rather that the manifold relations of force that take shape and come into play in the machinery of production, in families, limited groups and institutions, are the basis for wide-ranging effects of cleavage that run through the social body as a whole. (Foucault, 1979: 93–94)

Eco (1986: 244), however, argues that this radical rethinking of power by Foucault does not mean that it has no possible connections with language. Instead, Foucault's

image of power closely recalls the idea of the system that linguists call *the given language*. The given language is, true, coercive (it forbids me to say "I are him," under pain of being incomprehensible), but its coercion doesn't derive from an individual decision, or from some center that sends out rules in all directions: It is a social product, it originates as a constrictive apparatus precisely through general assent. . . . I'm not sure we can say that a given language is a device of power . . . but it is surely a model of power. (Emphasis added)

So, as an illustration of how far we have come now from formalist conceptions of discourse as language, we can now see that the linguistic system (the *langue*) itself, far from being the source of discourse, is just one instance of power where power is considered as a set of relations of force. Because these relations are local and historically contingent, they cannot be 'predicted' by a general theory. Only particular investigations – what the early Foucault calls 'archæological' investigations, investigations of a specific 'archive' – can specify them.

Returning to the level of the statement: statements are best approached not individually, but in terms of the organizations or archives of which they form a part. Hence, what can be said or not said about something is neither absolutely fixed (because it varies historically) nor open to the whims of the moment. For

the archive . . . determines that all these things said do not accumulate endlessly in an amorphous mass, nor are they inscribed in an unbroken linearity, nor do they disappear at the mercy of chance external accidents; but they are grouped together in distinct figures, composed together in accordance with multiple relations, maintained or blurred in accordance with specific regularities. (1972: 128)

Even though it can (by chance perhaps?) take a linguistic form, the statement is a sociohistorical function rather than a strictly linguistic one. Yet because statements can still be located in talk and texts, we can work from collections of statements to their organizing archives. This archaeological method shows that social histories of thought, knowledge, and power are both unique and specific as well as having general properties. Foucault (1981) called

this method of tracing the systematic (archival) properties of unique and local affairs 'eventalization.' It is no accident, then, that he refers to the archive as "the very root of the statement-*event*" (1972: 129; emphasis added).

However, Foucault's idea of the discursive archive does not simply replace concepts like 'system,' 'structure,' '*langue*,' and so on. Rather, analyses of an archive as a condition of 'stating,' as a relatively stable system of functioning (at specific places and times), must be taken together with analyses of its historical flux, of "the general system of the formation and transformation of statements" (1972: 130). 'Archive' is a much more mobile and fluid term than the relatively fixed concept of 'episteme' (1970). The concept of an archive "deprives us of our continuities" (1972: 131) and establishes the fact that human subjects and historical events are not firm and discrete (id)entities but are fragmented and changing sites across which the flows of power move – and sites that, in turn, themselves move the flows of power. The archive, more radically, "establishes that we are difference, that our reason is the difference of discourses, our history the history of difference, our selves the difference of masks" (1972: 131). Hence, in another work of self-commentary, Foucault (1978) argues for three radical modifications of our (then?) current conception of discourse.

Instead of thinking of discourse (in the singular) as a global 'language' pertaining to a global history, so that everything (even silence) refers back to a hidden 'meaning' that the historian or philosopher must find and interpret, Foucault argues that discourses (in the plural) are "limited practical domains" (1978: 16) that have their own "rules of formation" and "conditions of existence" (1978: 16). There is no meta-discourse, or higher discourse, that grounds specific discourses.

Instead of thinking that a totally free and unlimited human subject merely 'uses' the techniques of discourse to express itself, that is, to construct meanings from prelinguistic 'cognitions,' Foucault argues that the historian of ideas can find, as part and parcel of a discourse, "the operations exercised by different 'discoursing' subjects" (1978: 16). This is just one constituent of discourse analysis (as history of ideas). It gives no priority or privilege to the human subject, although it by no means, as in severe versions of structuralism, 'deletes' the subject (Althusser, 1976). In fact, in his later work, Foucault went on to give detailed attention to those discursive operations he called the techniques of the self and described what he was doing as the history of the human soul.

Instead of thinking that history once had a definite origin so deeply buried in the past that we have lost

touch with it, so that we must now remember it afresh as the 'real' starting point and purpose of humanity's 'being in the world,' Foucault suggests that history itself – the medium in which we are condemned to have our being – is differentiated and fragmented into particular discourses, and that each fragment (each discourse) has a temporal threshold, a process of coming-into-being, and an equally complex process of disappearance that can be analyzed and described.

For any Foucauldian approach, discourse then turns out to be more important than mere linguistic or social structure (or, indeed, their combinatory possibilities). It is intimately connected with the necessary historicity and finitude of our being in the world and the (perhaps paradoxical) fragility of that condition. It has, ultimately, to do with what we can know in any particular eventual circumstance – and how that knowing makes us what we are as historically located subjects. To make a travesty of a long-forgotten beer commercial: It refreshes the parts of our being that other discourse theories cannot reach.

Discourse, Narrative and Pragmatic Development

Discourse, Narrative, and Pragmatics

In linguistics, the term 'discourse' refers to a structural unit larger than the sentence. Of the many

definitions for it in a standard dictionary, linguistics picks out length and coherence as criterial. Discourse involves more than one sentence, and the sentences must be contingent. Just as every string of words is not a sentence, not every sequence of utterances is considered a 'text.' For discourse, there are requirements of relevance in form and especially in meaning. Texts can be created by more than one participant, as in conversation or in various

forms of monologue, most notably narrative and exposition.

The study of discourse is generally considered the province of pragmatics in that it involves the uses of sentences (the products of a syntax), when people attempt to communicate information. Analogous to 'syntactic competence,' learners must also develop 'communicative competence' (Hymes, 1972), where utterances are judged less in terms of form than with respect to how well they meet the requirements of various speech situations. However, to the extent that there are formal dependencies across sentences, for example, relationships of coreference or structural mappings governing ellipsis, the study of discourse may fall under syntax; and the description of degrees of relevance or coherence between sentences places it within various semantic frameworks. (Poetry, a specialized form of discourse, exploits sound patterns as well to create links between successive lines, but those phenomena are only rarely treated within phonology.)

Research on the acquisition of pragmatics in first language learning focuses on four major aspects of communicative competence.

1. Developing 'speech acts,' or the communicative functions of sentences in conversation. For example, using utterances to report events, make statements (or declarations) about the world, request information or action, or prohibit action (Dore, 1975; Searle, 1969).
2. Emerging 'conversational skills' in face-to-face verbal interaction. These include knowing when and how to take a turn in conversation; how to initiate, elaborate, or terminate a topic; and how to respond to a speaker in keeping with the pragmatic constraints set by the preceding utterance (e.g., direct question forms demand answers; indirect questions [*can you pass the salt?*] demand actions). They also include skills in detecting the presence and source of any breakdown in communication and knowing how to repair such breakdowns (Garvey, 1984; McTear, 1985).
3. Adjusting one's language to fit the social context of the conversation in keeping with cultural conventions and social roles. These involve issues of politeness, formality, and the age or status of one's listener in what have been called 'styles' or 'registers' of speech.
4. Taking an extended turn to tell a story ('narration'), explain an event, give directions on how to make something or how to get somewhere, or persuade one's listener in an argument ('exposition'). These are referred to as different 'genres' of extended discourse and require the organization of utterances into coherent and cohesive messages.

Early Pragmatics Development

A useful framework for understanding early pragmatics development derives from the theory of speech acts (Austin, 1962; Searle, 1969). According to Austin, speaking was 'doing things with words.' All sentences are speech acts, but the clearest illustration is the performance of those acts that can only be done with words, like promising or marrying. For example, the sentence *I now pronounce you husband and wife* is not a description of an event, but its utterance is the event. The marriage pact is not made until those words are spoken by a qualified person in the context of a wedding ceremony. In Austin's view, sentences have three components: intended function, 'illocutionary force'; form, 'locution'; and effect on the listener, or 'perlocution.'

By moving speech into the sphere of action, Speech Act theory points to nonverbal behaviors as precursors to speaking. Using the framework of Speech Acts, Bates *et al.* (1975) identified three phases in the earliest pragmatic development of children: the perlocutionary, illocutionary, and locutionary phases. For example, while stretching for something out of reach, an infant might make an involuntary effort noise. If the noise alerted a helpful adult to the child's activity, and she or he handed the object to the child, one could say that the child's behavior had an effect, but not that the child intended to communicate. The act would be perlocutionary, but not illocutionary. A slightly older child might look intently at the adult and grab for a toy in the adult's hand. Bates and her colleagues would have ascribed intention to the action with the intent look that accompanied it and called it illocutionary. The final locutionary phase begins when the child has the intention to communicate and uses words to do so (whether or not the perlocution, or effect, is the same as the one intended).

In this vein, Dore (1975) reported on a child in the one-word stage, who used intonation to change the illocutionary force of a single locution: 'mama' with a falling contour to name her, a rising contour to make a question, and an abrupt rise-fall to call her. As their linguistic repertory grows, children can move from 'protoimperatives' or 'protodeclaratives' to actual imperatives and assertions, and eventually to the whole range of functions that words make possible: requesting, prohibiting, greeting, cursing, promising, labeling, etc.

Conversation as Discourse

Among the pragmatic functions toddlers master toward the end of the second year, such as answering, repeating, and requesting, those that elicit further speech are key. When children can both speak and

elicit speech, they have the basic tools for creating discourse through conversation. Conversations in turn have sets of rules to be mastered.

Grice (1975) and Sacks *et al.* (1974) have described such sets of rules based on observations of successful and unsuccessful conversations. The most basic principles are (1) to take turns and (2) to be 'cooperative.' Grice defined cooperation in terms of four 'maxims,' the Maxims of Quantity, Quality, Relevance, and Manner. When it is a person's turn in conversation, his or her contribution should provide neither too much nor too little information, and it should be relevant, clear, and true.

The first of these behaviors to show development is 'turn-taking.' In many cultures, mothers will treat their infants and toddlers as conversational partners well before the children are capable of effective turn-taking. One may respond to the child's smiles and burps as well as his vocalizations, thus modeling responses in a turn-taking rhythm and extending periods of 'joint attention' with the child. Following another's gaze and establishing joint attention about an object appear to be themselves important precursors to conversation. Research shows that time spent in joint attention at six to eight months predicts later language measures (Mundy and Gomes, 1998). Indeed, periods of joint attention are the necessary context for conversation. Over the second year, children move from responding to others' vocalizations with actions to responding mostly with other vocalizations, i.e., conversing.

A second key to promoting conversation is learning to be relevant. The second speaker must make his or her responses share the first speaker's topic and add new information to it. As novice conversationalists, children depend heavily on assistance (or 'scaffolding') from their conversational partner. In general, children have been shown to respond more to questions than nonquestions, and the questions help by directing the nature of the response. Caregivers encourage children's contingent responses by asking questions and doing what Kaye and Charney (1980) called 'turnabouts,' turns that first respond to the child's prior utterance and then request further response. Still, the ability to give contingent responses, despite mothers' scaffolding of children's efforts, is slow to develop.

Preschool conversations between toddlers are tentative at best when neither party can reliably be relevant. Even in adult-child dialogue, 2-year-old children's responses tend to be mainly noncontingent. In a longitudinal study of dialogues between two young girls between the ages of four and six, McTear (1985) traced the emergence of greater and greater thematic continuity in their conversation as utterances came

to serve the dual role of responding to a preceding utterance, as well as providing for further talk. However, Dorval and Eckerman (1984) showed that second graders (8-year-olds) were nearly as likely to give noncontingent responses as contingent ones, with significant improvement not seen until fifth grade (age 11 or so).

Skill at conversational exchanges also involves being aware of when a turn is not successful. Efforts at repairing misunderstood turns are seen before age three (Garvey, 1984). The youngest children tend to simply repeat their failed messages, while children older than three are more likely to revise their messages (Tomasello *et al.*, 1984). 3- to 4-year-old children respond appropriately to a variety of requests for clarification from the caregiver, including those that request simply a repetition of an element of the child's utterance, a confirmation of what was heard, or further specification of an element in the child's message (Garvey, 1984). However, use of such clarification requests by the child herself to repair her own understanding is still inconsistent in the preschool years. In a variety of communication tasks, preschoolers often fail to question ambiguous information and do not themselves provide maximally informative messages (Garvey, 1984).

Finally, preschool children are also learning how to change their style, or register, of speech according to the needs and desires of their interlocutor. Politeness forms begin to emerge in 2-year-olds (Ervin-Tripp, 1977), who have demonstrated that they know to change the degree of directness of their requests when prompted to say it "even more nicely." 4-year-olds have also shown that they speak differently to a 2-year-old than to another 4-year-old or an adult, making some of the accommodations associated with motherese for the younger children (Hoff-Ginsberg and Kreuger, 1991). Where different dialects are involved, observers have recorded instances of code switching among 3- and 4-year-olds; the children used a more formal, mainstream dialect with adults, but more dialect features when addressing peers (Wyatt, 1991).

In the preschool years, children take many steps toward learning to produce discourse. In the context of conversation, they gradually move from observations and comments on ongoing activity to discussions of absent people and things involved in past or future events. That is, face-to-face conversation provides the option of using the nonlinguistic context to support the interpretation of what is being said. When the speaker cannot rely on the hearers having had the same experiences to help them understand the message, the speech must be more independent of the speaking context, or 'decontextualized.' It must

be more explicit and will typically require more complexity in syntax and cohesion (Tannen, 1982). Early moves to decontextualized speech in a conversational setting retain the potential benefit of interaction – questions and answers back and forth that help the speaker know what the hearer did not understand and to progressively refine her meaning. Thus, conversation provides both the motivation and the medium for children to take longer and longer solo turns.

From Conversation to Longer Texts, Narrative, and Expository

Longer turns in the context of scaffolded conversations with a mature speaker lead children toward their first narrative and expository texts. Narratives are essentially connected passages relating past events (Labov and Waletzky, 1967). Even among adults, they can commonly be ‘co-constructed’ in conversation with contributions from two or more participants, but a classic narrative is a self-contained production by one speaker (or writer).

Expository texts share many characteristics of narratives. They, too, are extended turns of decontextualized speech or writing, but their primary purpose is to convey information. There is no requirement that explanations relate events, although they often incorporate narrative passages. Different genres of exposition are more or less structured depending on their purposes and the amount of information that they need to package. A narrative or exposition must be structured to both impart information and govern the flow of the information. Through various linguistic forms, they distinguish what is background from what is highlighted, and what is given from what is new (Hickmann, 2003; Berman and Slobin, 1994).

Mature narratives present not only ‘what happened’ but further engage the listener in giving a perspective on the motivations and consequences of the events related. Using the same words and structures available for individual sentences, stories construct a ‘hierarchical framework’ for the whole text. For example, articles in English (*a* and *the*) identify definite versus nondefinite noun phrases within the sentence, but also function across sentences by signaling what is given (what has come before) from what is being currently introduced. Languages without articles, like Chinese, recruit other forms, e.g., word-order shifts, to perform the same functions (Hickmann, 2003). In both languages, such linguistic devices are ‘multifunctional,’ having one function within the sentence and at the same time another function in the discourse.

In addition, stories set up implicit expectations on the part of the narrator and also the characters

in them. Such expectations derive both from world knowledge, of the usual sequence of events, and from the particular circumstances of their setting in a given story. The economical expression of the different levels of perspective and expectation represented by the characters, distinct from those of the narrator, requires the integration of sophisticated cultural, linguistic, and cognitive skills by the speaker. The 5-year-old, often considered in command of his syntactic system, is still very much a novice in creating sustained discourse. Many of the elements of successful narration and exposition are still developing as children move into adolescence (Hickmann, 2003: 324).

Relatively little research has been done on children’s engagement with expository texts, although they clearly play an important part in their developing understanding of the world. The majority of children’s school texts outside of ‘language arts’ are exposition and there is perhaps reason to include it more in early education.

Narrative Development

Much more attention has been given to narrative in research and in early schooling. Labov (Labov and Waletzky, 1967) and later Bruner (1986) argued that narratives are a fundamental way in which humans encode and make sense of their experiences. It is a daunting task to understand and describe the many strands of development involved in the process of narration, but much progress has been made since Labov (Labov and Waletzky, 1967; Labov, 1972) brought the attention of linguists to naturally occurring narratives in people’s everyday lives and sought to apply the basic techniques of structural linguistic analysis to narrative functions. Just a few years later, Halliday and Hasan’s (1976) seminal work paved the way for focused study of microstructures, or the specific links creating cohesion across sentences.

The distinction between ‘cohesion’ and ‘coherence’ in narrative is generally framed in terms of the contrast between linear or ‘local’ versus hierarchical or ‘global’ discourse organization. So, “linguistic cohesion” is seen for the most part in adjacent clauses, while “thematic coherence” pertains more to macrostructures at the global level of plot organizations. By studying narratives from different languages and cultures, studies can use the contrast of stories made both within and across groups, finding elements subject to individual differences, and finding candidates for discourse universals in the commonalities of macro- and microstructures across cultures.

Looking at development across time of the ways discourse functions are mapped onto forms in the

stories of different age groups in different language communities, researchers have picked out a general progression of which functions are successfully encoded at what age. One can also see how different languages make encoding one or another function more or less difficult to achieve. For example, in English the presence of an early acquired inflectional morpheme for progressive aspect (*-ing*) encourages early marking of events as ongoing. In contrast, children learning German (German, Standard) or Hebrew, which both lack a similar inflection for aspect, do not have a comparable signal of the distinction and thus may be later in recognizing the need to recruit available forms for it, like adverbs (Berman and Slobin, 1994: 34).

Another area of important development in narratives involves the child's Theory of Mind (ToM). Bruner (1986) made the distinction between the "landscape of action" (i.e. the events that took place) and the "landscape of consciousness" (i.e., the protagonists' reactions, intentions, and interpretations of the events). The ability to understand and express the landscape of consciousness involves a child's growing awareness of and ability to reason about the mental states of other people (Astington, 1993) as well as the child's mastery of the language forms that refer to mental states, especially noun clause complements, e.g., "thinks that something is true," "does not believe what he sees" (de Villiers and de Villiers, 2000). Such clauses permit the expression of two propositions with different truth values in one sentence; for example, a false clause can be embedded in a true clause so that the narrator can express something about the character distinct from his own thoughts.

Research Frameworks for Narrative Development

Several comprehensive studies of narrative development have ensued in the last three decades. Some focused on the macrostructure of the event sequences in the form of 'story grammars': e.g., Labov himself (Labov and Waletzky, 1967; Labov, 1972), Mandler (1978), Stein (1982), Applebee (1978), McCabe and Peterson (1991). Others focused on the microstructure, and still others treated the relationships between micro- and macrostructure (Berman and Slobin, 1994; Hickmann, 2003).

Berman and Slobin (1994) merits particular attention in both the breadth and depth of their study, reported comprehensively in a 1994 volume, and in the host of studies their project has spawned. These 'frog stories,' like the pear stories (Chafe, 1980), the bear story (Snow *et al.*, 1995), the cat and horse

stories (Hickmann, 2003), and many others, use a single set of stimulus pictures presented to different populations under the same conditions. For example, Mayer's frog stories, especially *Frog, where are you?* (1969) have been told by adults and children of different ages, speaking languages of different typologies, with different language handicaps (Downs syndrome, deafness, Williams syndrome), different linguality (bi- and trilingual), and so forth.

Developing Narrative Coherence

Models of plot structure (or 'story grammars') provide the frame for describing and analyzing children's growth in coherence. Labov's influential schema (Labov and Waletzky, 1967) is one of the first to define the minimal characteristics of a well-formed story. It should have an onset, an unfolding, and a resolution (roughly, a beginning, middle, and end). In a later formulation (Labov, 1972), the onset of a fully formed narrative has an abstract, a brief statement of what the story is about, and it also provides an orientation or setting, the 'who, where, and when.' The unfolding is the obligatory nucleus of the story and consists of one or a series of complicating actions, which lead to a high point and then the resolution or result. At the end of the story, the narrator provides a coda, a short passage that indicates that the story is over and may bridge back to the conversation in which the story was embedded. In this schema, the strictly 'narrative' clauses recall the temporally ordered experience being recounted; the 'free' clauses or 'evaluative' elements have no fixed position in the text but occur throughout, and together give the motivation or commentary to the story. Evaluative statements convey the narrators' personal involvement in the story through expressing their own or the characters' desires, intentions, thoughts, or opinions – Bruner's 'landscape of consciousness.' Evaluation is found in 'free' clauses or can be embedded in the fixed narrative clauses in the form, for example, of intensifiers, similes, hypotheticals, etc., which go beyond a simple direct telling of what actually happened.

Stein's model (1982) was similar to Labov's but focused more attention on the unfolding components of the story. In her story grammar, after a 'setting,' there are 'episodes,' each with an 'initiating event' and an 'internal response,' which motivate an 'attempt' leading to a 'consequence' and resulting in a 'reaction.' One aspect of growth in children's stories, then, occurs in their progressively more complete episode structure. (See also Mandler, 1978; McCabe and Peterson, 1991; Trabasso and Rodkin, 1994; Berman and Slobin, 1994: Part IIa.)

Some authors have highlighted different schema for stories in various cultures and subcultures

(Gee, 1989). Still, a basic sequence for the development of children's ability to tell a story from a set of pictures, like those reported in Applebee, 1978, or Berman and Slobin, 1994, is more or less as follows:

1. 3- to 4-year-olds only occasionally provide minimal narrative sequences (two or three dynamic events related in a temporal chain), but more often respond to the request to "look at the pictures ... and then tell a story" with picture descriptions which treat each scene as an isolated event. Applebee (1978) elaborated further on pre-narrative development, characterizing children's most primitive stories as 'heaps,' lists of unrelated referents and events.
2. In a second phase, children organize 'chains' of events ordered in time. These tend to focus on the most salient pictures, rather than the events that advance the story.
3. Next, a 'causal structure' emerges (Trabasso and Rodkin, 1994). Early causal relationships generally begin by relating local or adjacent events and only later become more global.
4. At an intermediate level, children may manage one or two well-formed 'episodes,' but they are not able to sustain the organization throughout. Among the many stories analyzed by Peterson and McCabe (1991), one frequently seen category includes those that end at the high point, (i.e., do not manage to bring the story to a resolution).
5. The most mature stage projects a causal structure over the whole story, where events relate to an initial goal and attempts to reach the goal. The outcome is coordinated with respect to the goal and includes evaluative commentary, all organized in what Berman and Slobin (1994), following Guiora, called an 'action-structure' that communicates beyond its content through its organization the hierarchy of importance within the story.

Support for these stages also comes from studies of children's comprehension of and judgments about texts. Esperet (cited in Hickmann, 2003), for example, presented children with four types of candidate texts: (1) unconnected sentences; (2) event scripts, with a temporal order but no episodic structure; (3) incomplete stories; and (4) complete stories. Consistent with the findings from production studies, the 5- to 7-year-olds could differentiate true stories from unconnected sentences, but only the older children, the 9- to 11-year-olds showed sensitivity to the difference between complete and incomplete stories and scripts.

Well-formedness also appears to affect children's processing of stories. When subjects are presented with 'canonical' stories and stories where different

narrative units are deleted or displaced, even 5-year-olds will show better recall for the canonical stories, and generally will repair anomalous stories in retelling by making them more compatible with their canonical versions (Mandler, 1978).

Developing Narrative Cohesion

The most influential framework underlying discussions of development in this area derives from Halliday and Hasan's *Cohesion in English* (1976). They described (and proposed coding for) the micro-structure of a text, the 'semantic links' between elements across sentences. Halliday and Hasan presented a comprehensive taxonomy for five types of cohesion – Reference, Substitution, Ellipsis, Conjunction, and Lexical. They listed over a dozen subtypes for each, and in their coding indicated the direction, distance (number of intervening sentences) between the cohesive element and its source, and whether the link was direct or 'mediated,' i.e. linked to its source through another cohesive element that is also linked to the same source. Most links are considered to be 'anaphoric,' referring to an element in the preceding text, but can also be 'cataphoric,' referring to an element in text that follows. Reference that can be determined only from the situation outside the text is 'exophoric,' as opposed to textual or 'endophoric' links.

In general, as children get older, one sees fewer instances of deixis and exophoric references, and more connectivity within the text. The most crucial ties concern those that maintain 'reference' to the entities in the stories and those that locate the events in 'space' and 'time.' For tracking shifts in spatial location, one element is established as an 'anchor,' and then subsequent actions take place in some relation to the anchor. For time, the story sets a tense for the 'event time,' and then moves back and forth on a time line between the event time and the 'utterance time' (Hickmann, 2003).

The key principle is that the text, whether narrative or expository, must establish its own reference points in a way that does not presuppose prior knowledge of them. Once they are established, reference to them must be maintained consistently, until new elements are introduced and become available for 'presupposition' by subsequent elements. Managing presupposition is a task that requires both linguistic knowledge of the particular forms used in a given language and conceptual awareness of the knowledge state of the listener. For example, in English, use of the definite article *the* or a personal pronoun (*she*, *it*, *they*) presupposes an antecedent. To use them in a 'first mention' without an antecedent is anomalous or immature. But once an entity has been mentioned,

it becomes anomalous not to use the presupposing forms. Ex. *John returned from a trip. He brought news of his travels*, not **he brought news of a trip*. Younger children will generally use these forms in relation to their own knowledge base. In telling a narrative, though, the knowledge of the hearer is almost always different from that of the speaker, so the narrator must suppress his or her own reference points and maintain the ties from the listener's point of view – or in some cases, from the character's.

A fundamental error for young narrators is to use a presupposing form for first mention and indeed we see that 4- and 5-year-olds give appropriate 'newness marking' of first mentions at or below chance levels, whereas by nine or ten years old, they reach near adult levels (92%, Hickmann, 2003: 196). Note that young Chinese speakers have the same task of marking newness, but their language does this with word order, whether the element comes before or after the verb. Since word order has so many other functions linguistically, the task of marking newness is even more complicated for those learning Chinese.

Similarly, for 'maintaining reference' in English, one option is to use a zero form (ellipsis), e.g., 'He went up the rock and 0 called for the frog.' The choice of the null subject requires both discourse knowledge of when it is appropriate and syntactic knowledge of how to conjoin verb phrases. Berman and Slobin (1994: 181) reported that nearly all of the English preschoolers used null subjects in their stories, but not for discourse purposes. Unlike subject ellipsis among older narrators, the preschoolers used them either ungrammatically or conversationally, in response to questions their listeners used to prompt them to continue. Here, the obstacle appeared to be that the younger children had not completely mastered the conditions on phrasal conjunction ('he went and 0 called').

Cohesion is also enhanced by communicating a clear temporal order. Early stories tend to give no indication of the relative timing of events. By kindergarten, half of the children give adverbial sequencers like 'then,' 'and then,' or 'next.' By second grade or so, more children begin to use adverbial time clauses and create complex relationships between events (Pearson and Ciolli, 2004). (See also Berman and Slobin, 1994, for a description of the emergence of temporal links in the frog stories.)

Developing the Evaluative Function

Stories must have coherence and cohesion to be interpretable, but they must develop evaluative elements to be meaningful. Actions make the most sense when we know the actors' motivation and intentions, and stories are more engaging when they relate

the actors' emotions and desires and the narrator's reactions. The narrator must paint the 'landscape of consciousness' for the listener.

The earliest references to mental states in young children's narratives talk about the simple emotions or desires of the characters – happiness, sadness, fear, and anger in the case of emotion, and what they want or like in the case of desires. However, such expressions of mental state are still rather rare in the narratives of 5-year-olds although children at this age have a fairly well developed Theory of Mind (Astington, 1993). Between 5 and 9 years of age, children begin to incorporate more and more of the landscape of consciousness into their stories. More complex emotions like surprise, guilt, or jealousy, and references to the characters' cognitive states (what they believe, know, or are thinking about) begin to emerge (Berman and Slobin, 1994; Pearson and Ciolli, 2004).

Relation to Emerging Literacy

The relationship between Theory of Mind and discourse appears to be reciprocal. In order to tell an authentic story, rich with the internal reactions and cognitions of the characters, the child must have a conceptual understanding of mental states, a well-developed Theory of Mind. Similarly, a mature communicative competence requires the child to be able to judge the communicative intentions and desires of their interlocutors as well as infer their state of knowledge or ignorance about the topic of discourse. At the same time, the rich narratives that are told or read to children, and their active participation in back and forth conversation about them, provide developing children with some of the best evidence from which to build a Theory of Mind (Nelson, 1996).

Indeed, the pragmatic frameworks which guide the interaction of speakers in communicative situations build, with each new element of mastery, the tools to take the child to the next step, continually closer to adult norms for discourse. Many aspects of children's oral language predict their later skill with written discourse through the middle school years (Tabors *et al.*, 2001).

Discrimination and Language

J Baugh, Washington University St. Louis, MO, USA

© 2006 Elsevier Ltd. All rights reserved.

Various forms of linguistic discrimination throughout the world result from unique local circumstances. This article concentrates on linguistic perspectives, which intersect with historical, political, economic, educational, and other social influences that determine the stratification of dominant-to-subordinate groups everywhere. Those who hold political power tend to be linguistically dominant, and those who lack political clout are often linguistically subordinate. In some countries these sociopolitical linguistic circumstances become confused with popular conceptions of proper and improper uses of language (see Zentella, 1997).

Linguists from various backgrounds working in communities around the world have either directly or indirectly exposed forms of linguistic discrimination. Einar Haugen proved to be an exceptional pioneer regarding matters of linguistic discrimination derived from studies of bilingualism and its consequences. His article 'The stigmata of bilingualism' (Haugen, 1972) overtly recognizes that people who are fluent in two languages or who have partial competence in a second language speak with relative prestige based upon their fluency and the corresponding stature of those languages depending upon immediate circumstances.

Ferguson (1959) identified linguistic boundaries that coincided with related real or potential forms of language discrimination when he formulated the concept of diglossia, that is, where high and low forms of a language coexist with established linguistic functions regarding literacy, religion, education, etc. The 'High' (H) form is used for formal, religious, and scholarly purposes, while the 'Low' (L) form represents the colloquial vernacular that reflects many significant linguistic differences from the H form. He noted diglossia in Arabic, Greek, Swiss-German, and Haitian Creole, observing that the H form always had a strong formal literary tradition and that H was never acquired as a native dialect, but was always introduced through formal education.

Although Ferguson goes to great pains to restrict the concept of diglossia to H and L forms within a language, Fishman *et al.* (1971) found this concept to be so compelling that they extended it to include bilingual communities, such as those described by Haugen (1972). Linguistic purists often insist that diglossia must adhere to Ferguson's (1959) original monolingual depiction, albeit with explicit accounts

of the H and L forms. Others may be attracted to Cooper *et al.*'s (1971) extended definition, which has been applied to socially stratified bilingual communities in which H is aligned with the dominant language and L is associated with the subordinate language. Such a distinction has proved useful to bilingual scholars who seek to make clear differences between countries such as Canada, with two official languages that coexist in law, and the United States, where speakers of languages other than English confront greater linguistic disadvantages.

Thus far our orientation toward discrimination has focused on linguistic prejudice against people who are engaged in face-to-face (or telephonic) conversation, but there are other interpretations of linguistic discrimination that are more socially favorable when viewed in terms of those who are concerned with upholding linguistic standards. In this sense the Académie Française may be thought of as engaged in linguistic discrimination, in this instance, to ensure the purity and longevity of Standard French. While evidence of linguistic prescriptivism is abundant, another interpretation of linguistic discrimination can be found in the pioneering work of Brown and Gilman (1960), who observed that formal and informal uses of *tu* and *vous* in French resulted from a keen sense of social awareness about relations among individuals within the French speech community. Use of *tu* and *vous* was not only influenced by linguistic constraints, appropriate usage required the ability to discriminate between those who are peers of comparable or lower social standing, and interlocutors who are more senior and therefore deemed worthy of the more formal *vous*. Deferential kinship terms of reference require similar capacities to discriminate between those who are elder or younger among speakers of Chinese, Japanese, and Korean, among others. In Paris or Tokyo the native speaker of the local dominant language must discriminate between those who are deemed worthy of linguistic honorifics and those whose social standing is subordinate to that of the speaker.

Fastidious scholars have taken care to specify the forms of linguistic discrimination that can be gleaned from their research. One of the most illuminating accounts of research that helped dispel racial stereotypes about language can be found in Labov's groundbreaking essay 'The logic of nonstandard English' (Labov, 1972a). Labov (1972b) also used studies of American minority languages and dialects as the foundation for developing rigorous quantitative interdisciplinary studies of linguistic variation; he used conversational evidence as well as

speech that is strictly controlled under experimental conditions.

In the wake of the U.S. Civil War and ensuing racial strife that has lingered since the emancipation of American slaves, many unflattering and uninformed linguistic stereotypes and misconceptions about the intelligence of African-Americans has flourished and helped to perpetuate anti-black racism in America. Labov *et al.* (1968) built extensively upon Labov's major study of the social stratification of English in New York City (Labov, 1966). With support from programs intended to advance racial equality, Labov began the massive task of documenting the linguistic details of Puerto Rican and African-American English in New York City, and in so doing he challenged and debunked many of the prevailing myths about low intelligence among African Americans and those who have not learned English natively.

Many groups have experienced discrimination, but linguistic discrimination can be associated with individuals as well as groups. This article is devoted more broadly to groups of people who share voice qualities that belie their membership within one or more groups, that is, based on race, sex, sexual orientation, age, education, region, religion, ethnicity, class, etc. Goffman (1959) eloquently described the multiplicity of these groupings as they apply to individuals in their daily lives, as well as the various settings and situations in which individuals from one or more groups find themselves at any given moment.

Linguistic prejudice and discrimination frequently grow in postcolonial contexts that give rise to the birth of pidgin and creole languages (see Pennycook, 1998; Hymes, 1971; Romaine, 1988). Pidgins are born when two groups of speakers are in contact and draw upon features of their mother tongue and the unfamiliar language of their interlocutor. As such, a pidgin has no native speakers. However, once children acquire a pidgin language natively, it is transformed into a Creole. Throughout history most pidgins and the Creoles they gave birth to resulted from human conquests, where those who were enslaved and/or colonized came to speak nonstandard versions of foreign tongues that were spoken by more powerful colonizers or slave traders.

Linguistic stratification born of slavery, colonization, or other forms of human subjugation yields social conditions that repeatedly give rise to strong senses of linguistic superiority or inferiority that will vary greatly from one situation to another. For example, Trudgill (1982) observes 'covert prestige' associated with working-class speech in England, which at first blush may seem counterintuitive, however, the language of the popular masses will hold considerable

esteem to those who preserve it and nurture it through their daily language usage.

India represents a postcolonial nation where colonialism has left indelible linguistic impressions to the point that English still serves as a lingua franca throughout the country, while India's native languages are more strongly associated with diverse groups from different regions. This linguistic hierarchy may be replicated in other colonial contexts to which Indians migrated, such as South Africa (Mesthrie, 1992).

Changing political circumstances that transformed Europe when the former Soviet Union disbanded resulted in linguistic discrimination of a different kind. Reisigl and Wodak (2001) and Wodak and van Dijk (2000) observe profound linguistic opinions and overt anti-Semitism in the writing of journalists as western European nations absorbed growing populations of citizens from other eastern European countries. Indeed, the linguistic plight of immigrants in various communities frequently trigger negative reactions from locals who dislike the speech of foreigners. These linguistic opinions are relative and often exist within a nation, typically with clear knowledge of regions where speech is distinctive. In this way, a double-edged object may be forged, of linguistic adoration (among insiders) and potential linguistic ridicule (from outsiders).

Very often government language policies can exacerbate linguistic conflict or social coherence. Switzerland is well known for linguistic egalitarianism because of having four official languages, whereas official language movements that are highly nationalistic may, perhaps inadvertently, foster social conditions for intolerance against those who lack fluency in dominant linguistic norms.

While these observations are devoted centrally to linguistic matters that are clarified by linguistic research, anthropologists, educators, sociologists, psychologists, and many others confirm that linguistic discrimination intersects with other dimensions of social strife that accentuate linguistic behavior as a sign of inclusivity or exclusivity.

Discursive Practice Theory

B McElhinny and S Muehlmann, University of Toronto, Toronto, Ontario, Canada

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Practice theories try to account simultaneously for the ways that human action is constrained by the social-cultural order ('structure') as well as for human agency, which reproduces and/or transforms 'structure.' Key figures in the formulation of practice theory in the social sciences include Pierre Bourdieu (1977), Anthony Giddens (1979), and Michel de Certeau (1984), promising a way out of the enduring dichotomies between individual and totality, structure and agency, and activity and system.

Distinctive Features of Practice Theory in Linguistic Research

Two features distinguish practice theory as it has been developed in linguistic theory. First, in addition to the work of Bourdieu and Giddens, the work of Soviet psychology (especially the Vygotskian school of activity theory) (see **Activity Theory**; Vygotskij, Lev Semenovich) and Peircean semiotics has been particularly significant. Second, what structure might mean, and thus the tools needed to go beyond a structuralist theoretical model, varies more from work to work than in other disciplines; linguists often grapple with

the influence of social structure (the area focused on by practice-based accounts in most other disciplines), but sometimes they must also deal with the effects of grammatical structure or cognitive structure. In addition, they sometimes revisit ideas about the intersection of all three, for example in considering how language structures perceptions of the social world (especially in debates about the Sapir-Whorf hypothesis). Discursive practice theory often attempts to transcend the dichotomy between an objective view of language as a system unto itself (Saussure), and a subjective view, emphasizing the transitory creations of speaking subjects (phenomenological approaches). Also relevant are attempts to challenge dichotomies of type/token, form/use, synchrony/diachrony, and production/reception.

Practice theories challenge the view of social behavior as fundamentally ordered by rules and norms, which is evident in many formal and certain sociolinguistic approaches to language by focusing instead on the interplay of relatively stable schematic aspects of social life, and emergent, unformalizable ones. Instead of focusing on grammar, or even on the conventionalized, automatic correspondence between linguistic forms and context, a practice approach characterizes speech as a form of action, and language as fully interpenetrated by other modes of human engagement with the world (Hanks, 1996: 229–230). Practice theory thus effectively decenters language from its privileged place in linguistics.

In addition, while the unit of speech in formalist linguistic models is typically taken to be the isolable sentence of the individual speaker, in a practice approach it is the socially defined relation between agents and the social field that ‘produces’ speech forms (Hanks, 1996: 229–230). In this way, it rejects the attempt to reduce language use to conceptual models or individual psychology.

Two Examples of the Impact of Practice Theory in Linguistic Analysis

Genre Analysis

Genres are key units of description for the analysis of communicative practice. They are units greater than an utterance, but less than a language, and they are enduring conventions used to perceive the world and act on it (Hanks, 1996: 242). Earlier studies focused on structural definitions, trying to resolve which features constituted a sufficient or adequate basis for defining a genre (see Briggs and Bauman, 1992 for a review). Later studies, influenced by the ethnography of speaking and ethnosociology, investigated more locally relevant classifications but continued to use a taxonomic approach to classifying genre. Though Mikhail Bakhtin also used this approach, he also ‘challenged the notion that genres are static, stylistically homogeneous, and nonoverlapping units,’ and he introduced the need for considering the linguistic aspects of genres in terms of their ideologically mediated connections with social groups (Briggs and Bauman, 1992: 145). Hanks (1987) synthesized Bakhtin’s ‘sociological poetics’ and Pierre Bourdieu’s theory of practice, each of which he sees as inadequate on their own, to develop a notion of genre as an orienting framework for the production and reception of discourse. In his work, genres are not conceived of as unitary wholes, as in formalist approaches, but as schemes and strategies, focal elements which actors use variously and which never become fixed in structure. Hanks’s (1987, 1996) analysis of texts produced in early colonial Maya society in Mexico shows how novel genres were being produced at a time when social conventions of all kinds were contested. The focus on historical materials, however, forced him to extrapolate about conditions of production and reception when his own theory of practice would ultimately require a fuller account (see also Hanks’s (1990) detailed account of the relationship between deictics in Yucatec, which retheorized reference as a form of social practice).

Bauman and Briggs’s perspectives on genre emerged from an interest in creating more space for analysis of verbal artistry with the notion of perfor-

mance, which had some affinities with the notion of practice. A focus on performance also shifted attention away from the formal patterning and symbolic content of texts to the emergence of verbal art in social interactions between performers and audiences (Bauman and Briggs, 1990: 59–60). However, as they noted, a focus on performance could also risk simply broadening the focus of analysis without transforming it. They signaled a shift in focus from product to process and from structures to agency by focusing on entextualization, decontextualization, and contextualization instead of text and context (see also Silverstein and Urban, 1996). This focus emphasizes the intertextuality of genre, emphasizing the ways that interpretation of discourse is shaped by being linked with a genre. Crucially, however, not everyone has the power to engage in these processes: “by invoking a particular genre, producers of discourse assert... that they possess the authority needed to decontextualize discourse that bears these historical and social connections and to recontextualize it in the current discursive setting” (Briggs and Bauman, 1992: 148). These approaches both highlighted that genres cannot be understood in terms of form and function alone; analysis required addressing questions of political economy, ideology, and power, though the significance of ideology was better elaborated in Briggs and Bauman’s work.

Studies of Language and Gender In social theory, theories of practice have tended to focus more broadly on class relations, bureaucratic structures, or culture (Ortner, 1996). In sociolinguistics and linguistic anthropology, however, one of the key sites for the elaboration of practice theory has been in studies of language, gender, and sexuality. Feminist theorists challenge biologically or culturally reductive accounts of gender by pointing out that gender is not something one has but something one does. A variety of metaphors have arisen to capture this idea: gender as activity (Goodwin, 1990), performance (Hall, 1999), accomplishment (West and Fenstermaker, 1993), or practice (Eckert and McConnell-Ginet, 1992). Fine-grained sociolinguistic analysis seems to be particularly useful for demonstrating the way gender is done in everyday practices. Marjorie Harness Goodwin drew on Vygotskian psychology to argue that activities, rather than cultures, individuals, or gender, should be the basic unit of analysis for the study of interactive phenomena. Goodwin examined the different social structures created by African-American boys and girls in a range of speech and play activities. In some activities she found girls and boys building systematically different social organizations and gender identities, while in others

she found them building similar ones. Her focus on activities suggested that behavior is not the implementation of social scripts or cognitive schemata, but rather the (re)construction of each event anew as it unfolds. The focus on activities thus usefully replaces essentializing analytic categories. Nonetheless, like some phenomenological accounts, it also seems to accord speakers a lot of agency and tends to focus on gender as constructed in individuals vs. institutions, in a way which perhaps betrays the psychological origins of activity theory. Goodwin's focus on activities also left her work vulnerable to a critique more widely made of practice theory: that the move beyond the focus on the contingency and locality of practices towards an account of how these practices articulate with larger social systems is endlessly deferred (Connell, 1987; McElhinny, 2003; Smith, 1999).

The work of Penny Eckert and Sally McConnell-Ginet kept a macrosociological picture more clearly in focus, in part because their model was meant to challenge a structuralist-functionalist paradigm widely used in variationist sociolinguistics that places class at the center of analysis. Language has often been seen in this tradition as a passive marker of the speaker's place in the socioeconomic hierarchy (Eckert and McConnell-Ginet, 1992: 468). Eckert and McConnell-Ginet replaced a functionalist definition of community with the concept of community of practice. A community of practice "is an aggregate of people who come together around mutual engagement in an endeavor. Ways of doing things, ways of talking, beliefs, values, power relations – in short practices – emerge in the course of this mutual endeavor" (1992: 464). They argued that discussions of gender and other aspects of identity "all draw on reifications that emerge from and constitute conventional maps of social reality. These reifications structure perceptions and constrain (but do not completely determine) practice, and each is produced (often reproduced ...) through the experience of those perceptions and constraints in day-to-day life" (Eckert and McConnell-Ginet, 1995: 470). Eckert (2000) applied this concept to a study of a Detroit high school; Ehrlich (1997) applied it to studies of gender in second-language learning classrooms. A community of practice identifies a somewhat larger analytic domain than does activity, and it thus serves as a mediating region between local and global analysis. The notion of community of practice stops short, however, of social-theoretical analysis of large-scale inequalities (for some critical evaluations of the strengths and limits of the concept see Holmes and Meyerhoff, 1991).

Judith Butler's (1990) argument that gender works as a performative, constituting the very act that it performs, built on the definition of performative

utterances in Austin (1962) and Searle's (1969) work on speech act theory. Her argument that there is no prediscursive event, that even our understanding of biology is discursively produced, placed significant emphasis on what analysis of discourse might reveal about how speakers manipulate feminine and masculine ideologies. The utility of the concept of performativity for ethnographic and sociolinguistic work is currently debated, as is the contribution Butler's work made to practice theory (Hall, 1999; Livia and Hall, 1997; McIlvenny, 2002; McElhinny, 2003). Sometimes her work was seen as granting speakers too much agency (Cameron, 1997), but she had also been critiqued for failing to grant actors enough agency (Hall, 1999).

Conclusions

The critiques of Butler's work are representative of the way practice theory has generally been received. While practice theory emerged out of the conviction that it is possible to mediate between the opposed shortcomings of subjectivism and objectivism, the theoretical responses to this apparent antinomy are invariably met with the critique that they fail to transcend this dilemma. Bourdieu's work had been especially susceptible to this critique (Schatzki, 1997; King, 2000). King argued persuasively that Bourdieu's formulation of habitus, defined as enduring social knowledge in the form of unreflective habits and commonsense perceptions, slipped back into the objectivism it attempted to refute since the dispositions that comprise habitus are directly derived from individuals' socioeconomic or structural positions. Many sociolinguistic accounts which rely extensively on Bourdieu have yet to engage with this critique. Another strain of practice theory inspired by Ludwig Wittgenstein, Gilbert Ryle, and Martin Heidegger had called into question the possibility and relevance of theorizing practice in the first place (Stern, 2003: 187). These influences have, as yet, been less well-developed in linguistic theory, though see Duranti (1997) and Sidnell (2003). While this approach to practice theory may rightly caution against a re-theorizing of practice, it also points to the inherently precarious position that practice theory occupies. 'Practice' approaches attempt to offer a rigorous theory of society and to maintain an orientation that closely attends to the details of local organizations of activity. While this makes it useful in its promise to resolve analytic tensions, it also means that practice theory, perhaps appropriately enough, remains inchoate. For this reason some scholars have suggested that the insights of practice theory might be better understood as a project or method than a theory.

Education in a Multilingual Society

J Cummins, University of Toronto, Toronto, Canada

Introduction

Societal multilingualism can be conceptualized in relation to two broad dimensions:

- The proportion of citizens who are fluent in two or more languages
- The degree to which languages other than the dominant language are used for purposes of social interaction within the society.

Thus, the degree to which any society is multilingual varies in relation to how many of its citizens are fluent in multiple languages and use these languages for a variety of functions in a range of social contexts. By implication, few societies can be characterized as completely monolingual in the sense that virtually every society includes individuals who use their multiple language abilities in a variety of social contexts. There is no simple cut-off point above which a society can be characterized as 'multilingual' and below which it is 'monolingual'; rather, societal multilingualism represents a continuum that is, in principle, quantifiable according to the variables outlined above.

In an era of globalization with unprecedented human mobility and social exchange, processes of language learning (and language loss) are apparent in societies around the world. Government policies attempt to influence these processes by supporting the teaching of certain languages in schools and, in some cases, by actively discouraging the maintenance of other languages, usually the languages of subordinated groups within the society (Skutnabb-Kangas, 2000).

The complexity of global multilingualism, and the challenges of language planning, can be appreciated in relation to the fact that there are an estimated 5000 languages spoken in the world's 200 or so sovereign states and about two-thirds of all children in the world grow up in a bilingual or multilingual environment (Crystal, 1997). To illustrate, approximately half of the school populations in

the Canadian cities of Toronto and Vancouver come from non-English-speaking home backgrounds. Similar linguistic diversity as a result of immigration and population mobility characterize many cities in Europe, the United States, and Australia. Other countries around the world have always been highly multilingual since their inception as nation states (e.g., India, Singapore, South Africa, Switzerland, etc.).

In the following sections, categorizations of educational provision in multilingual societies are outlined, and some of the major sociopolitical and psychoeducational issues that characterize this provision are discussed.

Categorizing Education in Multilingual Societies

The most obvious initial categorization of education in multilingual societies is whether instruction is conducted through one language exclusively or through two or more languages. Although bilingual and trilingual programs have been increasing throughout the world, partly as a result of many positive evaluations of these programs (see below), the bulk of educational provision in multilingual societies is monolingual in nature. The relative merits of monolingual versus bilingual programs will be considered in relation to the research evidence after reviewing the many complex manifestations of bilingual and multilingual education.

A variety of typologies have been proposed for categorizing multilingual education. Perhaps the best known of these is Mackey's (1970) typology that distinguishes 90 different potential varieties depending on the intersection of home language(s), curricular organization of languages, and language(s) of the community and country, as well as the regional and international status of the various languages.

A less complex categorization was proposed by Cummins and Corson (1997). They distinguished five broad types based on the sociolinguistic characteristics of the languages used in the program and the population groups the program is intended to

serve. Four of these program types are intended primarily for minority or subordinated group students while the fifth is intended for majority or dominant group students. These categories are not rigid, and some programs can be located in more than one category as a result of the fact that the same program serves several different groups of students.

Type I programs involve the use of indigenous languages as media of instruction and are aimed primarily at helping students of indigenous heritage acquire or consolidate their knowledge of the language. Examples include Quecha/Spanish bilingual programs in South America (Hornberger, 1988), Maori bilingual and immersion programs in New Zealand (Bishop and Glynn, 1999) and the a variety of Native language bilingual programs in the United States (McCarty, 1997). The indigenous group has usually been conquered or colonized at some time in the past, and the bilingual programs are typically aimed at revitalization of languages whose survival is threatened.

Type II bilingual programs involve the use of a national language together with a higher status or more dominant language. The national languages involved in these programs typically have long-term status in the society and often some degree of official recognition. The primary target group of Type II programs are speakers of the national language, and the program goals typically include the development of bilingual and biliteracy skills among students and reinforcement of the status of the language in the society. Examples include programs that use various African languages together with English in several African countries (e.g., Nigeria and South Africa), Gaelic in Ireland and Scotland, Welsh in Wales, Basque and Catalan in Spain, and French outside of Quebec in Canada (Baker and Prys Jones, 1997).

Type III programs involve immigrant languages that are the languages of relatively recent immigrants to a host country. Many of the bilingual programs in countries such as the United States, The Netherlands, Australia, and Sweden fall into this category. Most of these are transitional programs designed to facilitate students' overall academic progress. In some situations, Type II and Type III programs merge into one another, as in the case of some Spanish-English bilingual programs in the United States that may serve both long-term Spanish-speaking groups as well as more recent immigrant groups.

Type IV programs use manual sign languages to serve children who are deaf or hard-of-hearing. Bilingual/bicultural programs for deaf children are a relatively recent phenomenon. Scandinavian countries pioneered bilingual/bicultural programs for deaf students (Mahshie, 1995) and North American programs involving American Sign Language (ASL) followed in the early 1990s (Gibson *et al.*, 1997).

Type V programs may involve either a national language or a language of wider communication and are intended for dominant or majority group students. The primary goal is to develop bilingual and biliteracy skills among these students. Examples of Type V programs include French immersion programs in Canada (Swain, 1997) and dual language programs in the United States (Thomas and Collier, 2002). Dual language programs in the United States also fall into the categories of Type II or Type III since they serve both linguistic minority students and English L1 students with the goal of promoting bilingualism and biliteracy for both groups. The European Schools model that involves instruction in up to four languages at various points in the students' school career also qualifies as Type V (Beardsmore, 1993). Many Type II programs involving instruction through a national language can also be classified as Type V because they serve students whose L1 is the majority or dominant language as well as native speakers of the national language.

Debates and Research on Bilingual Programs

Various rationales are typically offered for implementing monolingual education in multilingual contexts. These include justifications related to educational effectiveness, ideological imperatives, and administrative/financial expediency. For example, in Western countries with significant immigrant and/or minority populations (e.g., the United States) intense debates have raged with respect to the educational effectiveness of bilingual education. Those who champion monolingual education in the dominant language argue that maximum instructional exposure to that language will result in better overall school achievement. This argument is frequently paired with the ideological justification that education should actively promote the assimilation of minority students rather than encourage them to maintain their L1 and allegiance to their home cultures. Bilingual education in these contexts is also frequently characterized as costly and administratively cumbersome.

Debates in post-colonial contexts have covered similar ground, albeit with some differences. The educational effectiveness argument for monolingual education in the higher status language of wider communication is frequently fueled by parents' perception that this is the language of power and upward mobility. Ideological considerations that lead some governments to support monolingual education include the fact that in highly multilingual countries the former colonial language is viewed as 'neutral' and thus no favoritism is shown to competing national languages. Finally, the cost and administrative

burden of developing curricula and educating teachers to teach in multiple languages are frequently viewed as prohibitive for recently independent and often impoverished nations. As a consequence, it is often seen as more administratively feasible to teach through the colonial language than to explore multilingual instructional options.

Although the arguments for monolingual education have been persuasive to many policy-makers and parents in both developed and developing countries, accumulating research evidence paints a very different picture. Evaluations in many countries have demonstrated that well-implemented bilingual and trilingual programs succeed in developing fluency and literacy in a minority language at no cost to the development of academic skills in the majority or dominant language (Spolsky, 1986; Williams, 1996; Cenoz and Genesee, 1998; Cummins, 2000; Baker, 2001; Thomas and Collier, 2002). Furthermore, although there may be increased start-up costs involved in any new program, bilingual and trilingual programs are not intrinsically more costly to operate than monolingual programs. The fact that students in bilingual programs experience no adverse academic consequences despite less instructional time through the dominant language has been attributed to the demonstrated transfer of concepts and skills across languages (e.g., phonological awareness, concepts in content areas such as science and mathematics, reading and learning strategies, etc.) (see Baker, 2001 for a review).

In summary, considerable research supports the feasibility of bilingual and multilingual programs both from the perspective of cost and overall educational effectiveness. However, effective implementation is much more likely when the ideological conditions in the wider society are favorable. In the absence of such favorable ideological conditions, educators committed to the bilingual program must work collaboratively to create a microcosm within the school where students' bilingual and bicultural identities are affirmed (Freeman, 1998).

Educational Linguistics

N H Hornberger and F M Hult, University of Pennsylvania, Philadelphia, PA, USA

The Emergence of Educational Linguistics

By all accounts, educational linguistics as a defined area of study began in the 1970s with the work of Bernard Spolsky, who first put forth the term in a 1972 conference paper and later produced the seminal introductory monograph on the topic in 1978. He originally envisioned educational linguistics as a sub-field of linguistics, much like educational psychology and educational sociology are subfields of their disciplines proper, that would specifically address the broad range of issues related to language and education.

He positioned his educational linguistics in relation to applied linguistics, which, he noted, encompassed a broader territory of practical language issues. Educational linguistics has, indeed, continued to develop in tandem with applied linguistics, which has come a long way since the middle of the 20th century (Markee, 1990; van Lier, 1994). There is less than total agreement as to what the relationship between the two is, however. Some scholars, for example, identify themselves as linguists who are applied linguists who are educational linguists (e.g., van Lier 1997: 95), whereas others, pointing to its unique objectives and goals, distinguish educational linguistics as a field unto its own (e.g., Christie, 1994: 97; Hornberger, 2001: 5). What is clear, however, as Hornberger (2001: 19) points out, is that educational linguistics has developed a unique niche in that its “starting point is always the practice of education and the focus is squarely on (the role of) language (in) learning and teaching.” It is in filling this niche that educational linguistics has found its place in a variety of contexts around the world.

Three Schools

Internationally, educational linguistics seems to have taken shape in three major ways, or in what might be considered loosely the British, the Australian, and the American schools. Each is distinctive in a number of ways.

The British School may be the most closely coupled with general linguistics as seen in the efforts to make linguistics a foundational area of teacher training (Brumfit, 1997; Stubbs, 1986), as well as attempts to create curricula based on linguistic principles (Carter, 1990, cited in Christie, 1994: 96). At the

same time, British educational linguistics cannot be said simply to be the marriage of linguistics with education. On the one hand, there has not been universal agreement as to how linguistics should relate to education, leaving much to be done on this front by both linguists and educators (Hudson, 2004). On the other hand, following the lead of an applied linguistics that synthesizes multiple disciplinary approaches, British educational linguists also draw on a wide constellation of research tools beyond those offered by linguistics alone (Brumfit, 1996; see, for example, Creese, 2003).

Australian educational linguistics stands out for its clear connection to systemic functional linguistics, in particular. Here, systemic functional linguistics, in which language is viewed as a social semiotic that is part and parcel of creating and interpreting social context, is brought together with other social sciences in order to study language use in educational practice as a socially situated process (Christie, 1994; Martin, 1998). A central focus of the Australian School has been the teaching and learning of genre in literacy for professional and academic purposes (e.g., Christie and Martin, 1997). It also is worth pointing out the loose connection between the British and the Australian schools because of Halliday's influence on both the beginnings of British educational linguistics and the growth and development of educational linguistics in Australia (see Halliday *et al.*, 1964, for an early influential work; see also Hudson, 2002).

The American School is characterized by its diversity of topics and conceptual underpinnings. Aspects of general linguistics are brought together regularly with the research tools of other social sciences, most often anthropology, psychology, and sociology, to investigate the totality of issues related to language acquisition, language use, and sociolinguistic context in formal and informal education (Hornberger, 2001). In addition to Spolsky, Hymes has been an influential figure in American educational linguistics, especially in the early days, and his perspective on sociolinguistics (e.g., Hymes, 1974) has been drawn on in a great deal of research under the rubric of educational linguistics, especially in the United States.

It should be noted, of course, that the British, Australian, and U.S. contexts are not the only sites where educational linguistics has emerged. The principles of educational linguistics have been put to use in a variety of settings; for example, Pakir (1994) describes the use of educational linguistics to examine the role of multilingualism and cross-cultural communication for education in Singapore; and in Argentina, Suardiaz and Domínguez (1987) take an

educational linguistics perspective in considering the role of the native language in elementary education, as both instrument and object of the educational process and as means of evaluating that process. The importance of educational linguistics for other contexts also can be seen in the establishment of training programs in various parts of the world, which will be discussed later.

Taking Stock of the Field

Despite the clearly identifiable (albeit nonexclusive) trends in what we call the three schools of educational linguistics, there is much common ground and activity. Educational linguistics is characterized by certain core features that, by and large, all approaches to educational linguistics share. In particular, we highlight the tendency toward transdisciplinarity that, although latent in Spolsky's formulation, is increasingly gaining prominence. We then pause to reflect on academic and professional developments including the establishment of degree programs and the publication of core texts.

Defining Characteristics

Fundamentally, as Hornberger (2001) shows, educational linguistics can be characterized as a field with a dynamic relationship to a range of disciplines which takes a problem-oriented approach to issues focused squarely on language in or around education, yielding analytical scope with depth on these issues. Accordingly, educational linguistics has a broad scope and a narrow focus.

The interface of linguistics with other disciplines has always been a core feature of educational linguistics. As Spolsky remarks, it "start[s] with a specific problem and then looks to linguistics and other relevant disciplines for their contribution to its solution" (1978: 2). Its scope, he continues, "is the intersection of linguistics and related language sciences with formal and informal education" (1978: 2). The potential set of problems to be examined is, of course, unquestionably vast, as are the possible combinations of research tools that could be used to investigate them. This does not mean, however, that educational linguistics is adrift in an ocean of research prospects. Rather, as a field, it is "pluri-centric, multi-method, and multi-level" (Kjolseth, 1978, in reference to *Sociology of Language*). That is to say, there are, as several other entries in this encyclopedia indicate, multiple core issues at the heart of educational linguistics, which demand different sets of research methods. Thus, a broad scope is achieved through the range of work done under the auspices of the field and

depth is accomplished through intricate investigations by individuals with expertise in specific areas. Each educational linguist approaches research in different ways, some focusing on micro-level issues, some on macro-level issues, and others on the connections between them. The result is a holistic, or transdisciplinary, understanding of the interplay among individuals, language, society, and education.

From Interdisciplinary to Transdisciplinary

Educational linguistics came of age in a dynamic moment in intellectual activity, particularly in the area of language study which also saw the birth of Fishman's sociology of language (Fishman, 1968, 1972) and Hymes's ethnography of communication (Hymes, 1972; see Joseph, 2002, and Murray, 1998, for discussions on the history of [socio]linguistics). It is not surprising, then – given this climate that eschewed disciplinary boundaries in favor of the holistic study of specific issues – that educational linguistics emerged as problem-oriented and interdisciplinary. Spolsky suggested that linguistics, although central to the study of language-related issues, must be synthesized in a complementary manner with the approaches of other disciplines in order to comprehend fully any specific problem (viz. issue or theme) related to language and education (1978: 2–3). It is here that the seeds of transdisciplinarity in educational linguistics were first planted.

Writing on the subject of applied linguistics more broadly, Halliday (2001: 176) stated:

I say 'transdisciplinary' rather than 'inter-' or 'multidisciplinary' because the latter terms seem to me to imply that one still retains the disciplines as the locus of intellectual activity, while building bridges between them, or assembling them into a collection; whereas the real alternative is to supercede them, creating new forms of activity which are thematic rather than disciplinary in their orientation.

Halliday remarks that activities in applied linguistics "involve more than the content of any one discipline: at the very least, they involve psychology, sociology, and linguistics" (2001: 176) and he offers foreign language teaching as an example. In his call for a transdisciplinary applied linguistics, he notes that the aim should be not simply to create an amalgam of intellectual activity made up of a collection of features from a variety of disciplines but to go further and synthesize what each relevant discipline has to offer on a particular issue. By doing this, the focus becomes theme-based. A theme, he explains, "is defined not by content but by aspect, perspective or point of view" (Halliday, 2001: 176). In this way, Halliday suggests, the focus of intellectual activity

would not be on building bridges across disciplinary content areas but, rather, on synthesizing specific research tools (which are often, although not always, disciplinary-based) to investigate a particular theme or issue. It is a fine distinction but an important one.

The starting point is at the core of the difference between inter-/multidisciplinarity and transdisciplinarity. In inter-/multidisciplinary inquiry, the research begins with what is knowable from the point of view of specific disciplines and how, by building bridges across them, a researcher can achieve a more vibrant picture than one would be able to view from the vantage point of a single discipline alone. In a transdisciplinary orientation, research begins with a theme – an aspect (a specific issue, concern, problem) of a specific situation – and then uses the resources at one's disposal to investigate that theme. This, to use Halliday's words, removes the locus of intellectual activity from the disciplines, thereby superseding them to place the locus of intellectual activity around the theme itself. The transdisciplinary researcher is like a painter who creates a multidimensional picture of a particular theme by using the spectrum of research tools on her or his palette.

Following Spolsky's characterization of educational linguistics as problem-oriented, it is easy to see how it is best considered transdisciplinary. Problem-oriented is similar in spirit to theme-based in Halliday's formulation of transdisciplinarity. In each case, the idea is that a researcher not simply takes disciplinary knowledge and applies it to a situation. In educational linguistics, a researcher begins with a problem, issue or theme, related to language and education and then synthesizes the research tools in her/his intellectual repertoire to investigate or explore it. The work of educational linguistics, then, is carried out in and across a variety of academic departments (anthropology, area studies, education, English, foreign languages, linguistics, psychology, sociology, etc.) depending on the theme. This is, incidentally, how the pioneering anthropological linguist Edward Sapir envisioned that *all* research in linguistics should take place (Anderson, 1985: 219–221). In this way, educational linguistics follows in a tradition of linguistics broadly conceived. The Australian School has long taken this approach, characterizing educational linguistics as a transdiscipline (Martin, 1993: 141).

The theme-based nature of a transdisciplinary educational linguistics also serves to highlight another crucial element of this field – research/practice reflexivity. Research in educational linguistics is not done for the sake of knowledge alone but, rather, with the aim of addressing a particular aspect of a practical concern to formal and/or informal language education. Thus, the aim of research is to impact on

practice. This is a two-way street, however. What is done in the practice of formal and/or informal education often serves as the impetus for research. In this way, themes to be investigated are not generated exclusively in the mind of a researcher but from the researcher's contact with practice. In educational linguistics research and practice feed off of as well as inform each other (Freeman, 1994; Myers, 1994; Pica, 1994).

From its beginnings, the field of educational linguistics has been concerned with the study of all the factors that influence language use as it relates to education. The objective has always been the creation of a thorough and articulated body of knowledge about these factors, and relationships among them, for the purpose of advancing educational issues ranging from language acquisition to language planning. Clearly, no single paradigm or discipline could suffice for such an endeavor and, consequently, educational linguistics is likely to continue to evolve as a transdisciplinary field, bound not by a disciplinary base but by its single focus.

Professional Activities

Since the founding in the early 1970s of the first two doctoral programs in educational linguistics at the University of New Mexico, by Spolsky, and at the University of Pennsylvania, by Hymes and Wolfson (Hornberger 2001), a number of academic training programs specifically in educational linguistics have grown around the world. Doctoral programs with a concentration in educational linguistics have been established at Arizona State University, Stanford University, the University of Manchester, the University of Newcastle upon Tyne, and the University of Warwick. Master's level training in educational linguistics has been created at Lancaster University, Srinakharin Wirot University, and the University of Colorado, Boulder. Coursework in educational linguistics is offered at universities in Australia, Canada, New Zealand, Saudi Arabia, the United States, and probably elsewhere as well. In addition, the University of Groningen hosts the Educational Linguistics Research Group and the Monterey Institute of International Studies offers master's degrees in TESOL and TEFL through its Graduate School of Language and Educational Linguistics. Educational linguistics is clearly becoming firmly institutionalized (see Relevant websites).

Intellectual activity in educational linguistics also has been strong since the early 1970s. The first foundational book, alluded to earlier, was Spolsky's (1978) *Educational linguistics: an introduction* followed by Stubbs's (1986) *Educational linguistics*.

Developments continued in the 1990s when educational linguistics was a featured topic of the Georgetown University Round Table on Languages and Linguistics (Alatis, 1994) as well as the subject of other conference presentations (e.g., Brumfit, 1996; van Lier, 1999). The *Concise encyclopedia of educational linguistics*, an impressive summary of work in the field, edited by Spolsky, was released in 1999. Most recently, Kluwer Academic Publishers inaugurated its *Educational linguistics* book series with van Lier as general editor. Although there is as yet no professional organization or peer-reviewed journal devoted to educational linguistics, the student-managed *Working Papers in Educational Linguistics* (www.wpel.net) has continuously published work since 1984. Individual educational linguists have published and presented their work in a variety of venues since the beginning and they continue to have a strong presence in linguistics and related social sciences.

Future Directions

Lamentably, as Gee reminds us, “linguistics has had much less impact on education, and teachers know much less about language and linguistics, than the current state of our knowledge about language in education, or the current dilemmas of our schools, would seem to merit” (2001: 647). After depicting how differing theories of language arising from functional and generativist linguistics, respectively, play a role in major educational debates (such as that around whole language vs. phonics instruction), Gee goes on to exemplify some of what we do know about language in education, including the role of overt focus on language in helping children acquire new forms of academic language, the need for teachers to understand the diverse linguistic and cultural resources children bring to their classrooms, and the ways in which language form and meaning are interactionally worked out in moment to moment classroom interaction. He argues, then, as other educational linguists have before him, that we need to do a better job of putting what we know in linguistics into practice in schools.

As pressure builds on the educational systems of the world to serve the needs of increasingly diverse multilingual populations and at a time when multilingualism and multiliteracy are clearly becoming socially and economically advantageous, the need to understand relationships between language and education is particularly acute. The more the complexity of the relationships between language and education is recognized, the more complex research must become, in turn. Transdisciplinary work is likely to be more important than ever before. Although educational linguistics as a field has tended in this direction since

the beginning, there is much to be done to build a truly unified and coherent body of knowledge. Although all educational linguists seem to share the common goal of fostering education that is linguistically appropriate and socially responsible, there is little strategic dialogue on how to realize this goal on a grand scale. As a whole, then, educational linguistics seems to lack a clear course. If educational linguistics is to emerge as an articulated transdiscipline that encompasses all issues in language and education, it is time to seek out the connections and relationships among all the individual and societal topics that are studied at micro-, meso-, and macro-levels. Recent trends in ecological research are promising in this regard.

Although ecological approaches are not new to the social sciences, they have recently gained prominence in educational linguistics. Van Lier (1999), for example, emphasized the importance of integrated multidimensional inquiry over the decontextualized study of discrete variables when trying to understand matters related to language and education, which are all socially situated. In this vein, an ecological approach is increasingly used in the study of all facets of educational linguistics, from individual-level language acquisition to classroom pedagogy to language policy. For instance, Leather and van Dam’s (2003) *Ecology of language acquisition*, the first text released in Kluwer’s *Educational linguistics* series, features a collection of articles that consider the complex contextual factors that influence language acquisition. In addition, Hornberger’s (2003) *Continua of biliteracy: an ecological framework for educational policy, research, and practice in multilingual settings*, also an edited volume, highlights the value of synthesizing multiple levels of analysis in order to fathom the intricacies of constructing, implementing, and evaluating educational programs for bi-/multilingualism. Although these books reflect different perspectives on ecology, they share the understanding that the processes involved in any aspect of language and education cannot be effectively studied in isolation. It is in this sense that ecology is likely to play a central role in the future of educational linguistics.

Consistent with the early core characteristics of the field, these ecological approaches in educational linguistics are problem-oriented and interdisciplinary. At the same time, the theme-focused holism in these approaches moves the field more firmly toward transdisciplinarity, making a strength of drawing on multiple disciplines to create a holistic portrait of (the role of) language (in) teaching and learning. In all, educational linguistics, as it has done throughout its short history, is certain to remain grounded in its core principles while adapting to fit the needs of research and practice in an ever-changing multilingual world.

E-mail, Internet, Chatroom Talk: Pragmatics

D Stein, Heinrich-Heine-Universität Düsseldorf, Düsseldorf, Germany

© 2006 Elsevier Ltd. All rights reserved.

Scope and Purpose

The notion of the Internet comprises several elements: the ensemble of technical possibilities resulting from computers being linked to each other in computer networks; the types of communicative situations and types of language used in those situations; the body total of its users; and the sum of all Net communities using language. All of these elements define situations of language use. In addition, the Internet comprises all websites, which may be linked to all kinds of use situations. This article will deal exclusively with uses that situations such as chats, e-mail, and lists have in common. All of these genres essentially involve the use of language in an interactive, human-to-human way.

The following discussion will only deal with interactive Internet genres. Just as in written and spoken language, there are great differences between these genres; the following discussion will try to identify aspects of language that apply to all such genres, even if to varying degrees, in the same way that we can make useful generalizing statements about written and spoken language as basic medial varieties. The following discussion will include technical details of the Internet only to the extent that such details are needed to account for specific uses of language on the Internet. The discussion presupposes a basic knowledge of the Internet and its resources.

Research Background

The rise of the Internet as a medium for communication has, next to its societal, economic, and political consequences, arguably had the most significant effect on language. Although the rise of the Internet has variously been compared, as to its nature and its

effects, to the rise of mass literacy in the ‘Gutenberg revolution,’ the new cultural technology represented by Internet communication has received surprisingly little attention from linguistics. On the one hand, Crystal (2001: viii) points to the eminently “linguistic character” of the “Internet revolution,” which he characterizes as a “linguistic revolution” (Crystal, 2001: viii); on the other hand, there is a remarkable reluctance on the part of linguists to engage in the subject to any major extent, when it comes to taking a perspective on the language of the Internet vis-à-vis the other medial varieties of language (such as has been done with respect to the differences between the spoken and written medial varieties of language). In fact, the common theme of all research on the subject is to point out how this lack of research interest is in stark contrast to the role of the Internet itself.

Several factors may be cited as possible motivation for this unexpected reticence on the part of the linguists. The use of language on the Internet occurs in the most technically-oriented among all of the media and, as such, is removed from what linguists tend to perceive as the domain of ‘natural’ language occurrence, given that the study of natural language is supposed to provide a window to humankind. The Internet’s high degree of technological sophistication is felt as too much of an intervening, disturbing factor. Another factor may be the nature of the medium itself: given the fast technological development of the Internet, statements about communication on the Internet tend to become obsolete at a rate much faster than in any other field of language studies, in fact faster than in any other area of scientific investigation.

The relative volatility of the object of study is another reason why research on language in the Internet has been less well represented in traditional publication channels, which take a relatively long time for publication. This, in turn, has prevented the field from becoming an established and reputable field early on. It has also not been helpful that

most of the research on computer-mediated communication (CMC) has occurred on the fringes of many other disciplinary traditions, often making it difficult to locate previous work on the topic. In addition, much, if not most, of the early work has seen the light of day in student papers and M.A. theses, available, befittingly, through the Internet. All this made for a distinct – and in fact embarrassing – lack of genuine linguistic interest in language on the Internet.

During the first stages of research on the Internet, there was a lot of speculative popular comment, practical interest in the technicalities of the Internet, and cultural criticism, most of which bordered on linguistics, and in fact pointed up the need for an empirically based linguistic study. Beginning from the earliest stages of the Internet, there continues to be a strong interest in practical etiquette, which includes matters linguistic, but is arguably just as interesting in its own right as a field for (socio-) linguistic research. While the social sciences showed an early strong interest (which also was of relevance to linguistics; cf. Wallace, 1999; Döring, 2003), the first major representatives of genuinely linguistic research are found in the studies by Herring (1996), Weingarten (1997) and Beißwenger (2000). The most recent – and in fact the first – monograph on linguistic aspects in the narrower sense is Crystal (2001). This work reflects the fast pace of the development of the Internet in that the research quoted is represented to a great extent by contributions to on-line journals (e-journals), which have a much faster rate of publication than do the traditional channels. The well-established *Journal of Computer-Mediated Communication* is supplemented by a website called *language@internet*, devoted specifically to research on language and language use on the Internet.

Finally and most significantly, empirical work on language in the Internet has up to now shown a severe bias towards a few world languages, with English and German the subjects of, by far, the most empirical studies. As this fact has definitely resulted in a skewed view of the subject, it should be clearly stated at the outset that whatever is said in the following reflects this present stage of scant empirical research – shortcomings of a kind and a degree that are unusual in other fields of linguistics. There is a very urgent need for studying other, typologically and culturally different, languages, as such languages are increasingly making an appearance on the Internet.

Languages on the Internet

Before discussing linguistic aspects of language on the Internet, it is in order to address the issue of languages

on the Internet. While it is obviously very difficult, for a number of reasons, to give any figures even approaching reliability (language of home pages? language of chats, of newsgroups, listservs, e-mail? an average of all these? frequency of use?), it is generally agreed that at the moment of writing, English is (still) the dominant language in the Internet, certainly as far as the language of homepages and the languages of browsers are concerned. There appears to be a consensus that, as of now, the figure for English stands at between 70 and 80%, with Spanish as the current runner-up. Even so, the rate of change in favor of other languages is enormous.

While English clearly has a major advantage as the language of the technology of the Internet – all terms for technology and communicational procedures being in English – there are countervailing tendencies. Above all, the number of Internet users whose first language is not English has risen dramatically; it is now estimated to be in the area of two-thirds of all Internet users. The issue here is to what extent these users are using which language in communicating with whom. Again, English is bound to have a major advantage for communicating with speakers of other non-English languages, both because the technology and terminology are English and because of the difficulties of introducing other writing systems. Still, there is a distinct and (even within the space of only a few years) fast increase in the number of other languages being used on the web, with Chinese as a potential frontrunner in the foreseeable future. Other factors that have to be taken into account are the global cultural and political reactions against English and English-speaking countries, along with the globalization process itself, inasmuch as English and the Internet represent important vehicles as well as symptoms of this process.

While further aspects of linguistic change will variously be taken up in the following sections, it is clear that on the level of language alone, the new medium is having a major impact on the ecology of language (see **Adaptability in Human-Computer Interaction**). The trend towards the use of English as a lingua franca on a hitherto unprecedented scale will be counterbalanced, with effects difficult to predict, by a slowing down, if not a reversal of the universal trend towards language loss, especially of minority languages (see **Minorities and Language**). What at the moment looks like a clear dominance of English on the Internet with the concomitant political, social, and cultural effects of language convergence will within a relatively short period transform into a major effect of preservation of language diversity, with the Internet offering a sanctuary for otherwise doomed languages and providing them with an important tool for

the preservation of their identity, something no other medium could offer. It is difficult to predict, however, if all types of languages will be affected to the same extent and in the same way. Given the novelty of the situation and the fast rate of change of usage conditions, including the technical facilities, it is hard to predict if the effects will include a global diglossia, involving English or other world languages, or what the scenario of language distribution on the Internet and other linguistic media will be.

Language in the Technical Medium

Of all three language media, the Internet is the one that is the most highly technically, nonnaturally constrained. It is therefore to be expected that to a considerable extent, the specific shape of language on the Internet will be a consequence of these constraints. While a radical technological determinism is not advocated by anyone, it is equally clear that the language of the Internet, for all its internal diversity, is shaped by the technological conditions in the same way that spoken and written language are. Here, it may be useful to work with a three-tiered layering of basic constraining factors: just as the differences in the physical, pragmatic, and communicative situation or setting of the two traditional language media make for differences in the social, psychological, and emotional conditions and perceptions of the situation, and, as a consequence, trigger different choices from the repertoire of structurally possible forms, so, too, the specific technical and physical conditions of Internet communication will result in specific constellations, comprising

- the physical setting
- the communicative situations and situations of use that are based on this setting, along with the situations as they are perceived psychologically, socially, and emotionally, and the concomitant pragmatic conditions
- the choices made from the repertoire of available linguistic forms, these choices in turn providing access to the perception of the communicative situations.

This three-tiered framework provides a broad grid for the new options and choices on all levels of linguistic analysis: from new genres to the systematic choice of the individual items.

Since every discussion of the place of language in the new medium makes reference, in a variety of ways, to the physical conditions and the communicative situation on the Internet as explanatory dimensions for the specifics of language use, it seems appropriate to briefly discuss these constraints first.

Next to the outstandingly 'technical' character of the medium itself, including its one-to-many and one-to-one, as well as all kinds of combined situations, the immense speed of communication and the sheer quantitative possibilities of data transfer, the most important physical conditions determining the Internet setting are absence of physical copresence and various forms of shifted temporal copresence. Chat situations and instant messaging, as well as MUDs and MOOs (see below), come as close as possible to temporal copresence (either synchronous or asynchronous), whereas in other forms, such as e-mail, we have a presumption of temporal proximity (in replying and reacting) that varies to degrees; in contrast, listservs and newsgroups have a lesser expectation of their entries being followed up.

The lack of physical copresence has consequences of various kinds. Physical distance has been thought, on the one hand, to be prone to translate as emotional distance, making communication on the Internet appear less apt for subjective and personal communication. On the other hand, the intervening technology, together with, e.g., the option of assuming anonymous nicknames in chatrooms, provides a protective wall, allowing one to take more risks in communicating, at the same time that it reduces the need for strict self-control. This permissive character of the Internet in turn provides for more personal freedom than does spoken, face-to-face communication. These perceptions of the communicative situation have immediate consequences for the linguistic behavior of individuals, and are reflected by it.

This lack of control and monitoring has led to what, from a normative point of view, may appear as a relaxation of linguistic decorum and in general, more liberal attitudes towards norms, linguistic and social. In addition, the inability to control the other communicants provides more freedom and room for creativity, more room for playfulness, but also defines new constraints. It is not the case that there are no norms. Rather, Net communities on all levels develop norms that stand in a complex relationship of difference and distance to the norms in other social situations. The language used reflects this perception of the communicative situation as a virtual, shared communicative place (or even a 'stage') with newly evolving norms on several levels.

In fact, one of the major gratifications of Internet use, be it in chats or virtual play rooms such as MUDs (Multi-User Domains) and MOOs (Multi-Object-Oriented Multi-User Domains), is the sense of theatricality or even drama that is conveyed by the specific virtual universe of discourse and its complex relationship to the real world – not unlike, one might even argue, to what happens in literature. It is

this theatrical character of the Internet that goes a long way towards accounting for the playfulness, the creativity of language, and in fact the humor typical of much Internet language, which is also the hotbed of the specific linguistic developments on the Internet. (Further, pragmatic implications of this characteristic with respect to speech acts will be discussed below).

Substituting Nonlinguistic Contextual Information

The linguistic issue that has figured most prominently in the discussions of language in the Internet is its character as a medium situated in between, and having affinities to, both spoken and written language. Already in the earliest linguistic analyses of Internet language, the issue most focused on was the presence of elements (especially in the language of chats) that are typical for spoken language. Such forms have to be seen under two angles: as elements conveying playfulness and creativity, and as elements substituting for the nonverbal context; at the same time, these elements carry the germs of potential linguistic changes. Among these elements are: ideograms (called 'emoticons'), expressing emotion in a way that is iconic for the respective facial expression; the liberal use of expressive abbreviations (such as 'rotfl,' 'rolling on the floor laughing'); and onomatopoeic expressions (or sound words) like 'ahhhhhhhhhhhhhhhhh'. The list also includes all kinds of phonetic spellings (e.g., 'paske' for French 'parce que').

Orthography, too, may be an expressive vehicle; it is used in many ways, such as variation on capitalization (for emphasis) and use of lower case where (as for German substantives) upper case is standard. Punctuation and spelling deviations are also used in very creative ways.

Typical for chatrooms are, furthermore, activities termed 'emoting,' or action descriptions such as 'looks.' Typing 'me looks bewildered' will appear on the screen as 'X looks bewildered.'

The above list awaits further empirical study across typologically different languages, since different languages appear to make use of typologically different structures. A salient feature of German Internet language are the so-called 'roots,' 'action words,' or 'inflectives' as in *knuddel* ('cuddle'), which even can be intensified to *megazurueckknuddel* ('mega cuddle to you too'). These forms are formally infinitives and are therefore not inflected. This type of verbalization performs the respective motions (or emotions) and has to be seen in the context of the 'theatrical' character of the Internet universe of discourse.

Most of the forms quoted here have developed into markers of registers belonging to the Internet language of the languages under discussion (*see Register: Overview*). Their frequency of occurrence correlates with the perceived formality of the type of interaction, even within subtypes of individual genres, such as different types of chat scenarios (e.g., moderated vs. nonmoderated). The use and mastery of these items have developed into indexes of speech community membership, with some Internet genres, like MOOs and chats, having developed very elaborate and strictly enforced social conventions. There is, on the Net, an acute perception of community membership as manifested by the correct use of these items.

Apart from their creativity in the specific communicative situation of the Internet, these novel items (especially the typically oral ones) have to be seen in the light of the language's particular character as medium. The most salient characteristic from the point of view of pragmatics and context is a property often referred to as 'lean': the Internet is characterized as a 'lean medium,' referring to the fact that in this medium, there is no 'rich' contextual information available of the extralinguistic kind. (The issue is similar to that discussed in earlier sociolinguistic debates under the label of 'deficit' vs. 'difference'.) Even so, the validity of the lean medium hypothesis has been questioned by people who claim that the screen provides a variety of graphic means to make up for the lack of extralinguistic contextual information; among these are the emoticons and other devices referred to above. Other ways to signal identity comprise (linguistic and other) features, such as personal formatting and the choice of nicknames, to compensate for the types of information not available in the Internet language, as compared to the spoken and written media.

The fact remains, however, that more attention is focused on the individual graphic and linguistic item chosen: the individual item and variant is perceived as carrying a higher functional and informational load. After all, with respect to perception and processing, the Internet language's visual input has a specific addressee and its shape cannot be changed at will: once received, it has much less of an ephemeral character than does the acoustic input of spoken language. In addition, it has been observed that the Internet medium, in comparison with the two traditional media, is much more conducive to metalinguistic comment and as such, much more self-reflexive; this observation holds both in terms of reflection on, and meta-discussion of, issues of language use proper, as well as for the pragmatic and social rules that govern language behavior (arguably another consequence of

the medium's high technological sophistication). Thus, the technical nature of the medium changes the language itself, both as to content and use.

As for empirical research on the language of the Internet itself, one of the glaring deficits in this area concerns the lack of a cross-linguistic investigation of the features and forms discussed above. Even a superficial survey of extant work reveals that the forms used in a given language or culture are not only technically specified, but vary in accordance with typological conditions, with specific national cultural histories, and with the varying situations of contact. The use of uninflected forms in French appears to be very rare, whereas it is very frequent in German: in a strongly inflected language such as German, absence of inflection is marked and carries information. This condition would in turn explain the paucity of these forms in English, with empirically testable claims following from this hypothesis. As for the English of the Internet, this is characterized by its well-known proliferation of abbreviations, a phenomenon that fits in well with the language's established structural tendency of abbreviation and morphological reduction generally. It is instructive to observe the dominance of English as it appears even in the transfer of English-based abbreviations to other languages (among these not least German), as observed in the use of abbreviations and acronyms, such as 'rotfl' ('rolling on the floor laughing') even in German chats, 'cu' (for 'see you') or in French chats; (cf. Haase, 2003; for work on Italian, cf. Orletti, 2004).

In cultural terms, the high frequency of acronyms in English may go back to the culture's long-established tradition of using shorthand in telecommunication. On the other hand, the typical German use of uninflected expression may well represent a borrowing from English-language cartoons and comic strips, whereas the French preference for the 'plus' and 'minus' signs ('+', '-') may reflect the prestigious position of mathematics in the history and the educational system of that country. There is thus a wide-open field for the crosslinguistic study of technical-based universal, cultural, and typological factors determining the language-specific make-up of 'Netspeak' in Crystal's (2001) terms.

The Status of Internet Language as a Medium: Between Written and Oral, or How?

Apart from the forms directly supposed to act as substitutions for contextually given information in spoken language, there is another group of forms that are characterized by their preferred occurrence in spoken language. Here, we find all kinds of ellipses

and deletions (both of subject and auxiliary, as in 'been here today?'), particles, deletions, and interjections as well as paratactic style and colloquialisms. Together with the first group of forms (treated above under the heading of 'lean' medium), they contribute to what has been discussed as the typical 'oral' flavor of much of Internet language, especially as it is used in chat.

The two groups have given rise to a debate that basically replicates and extends the familiar issue of orality vs. literacy. The discussion has increasingly focused on the question of whether the language of the Internet is a new variety of language medium in its own right, on a par with varieties such as the spoken and written medium, or whether it is simply an extension of written language, since it is typed on a keyboard, but of course including spoken elements to varying degrees. To deal properly with this matter, an essential distinction must be made between the medium of the physical input and output on the one hand, and on the other, the technicalities of the transmission process, which result in the properties discussed above. In particular, the way the language is dealt with through the media of writing and reading, in production and reception respectively, has led researchers to characterize Internet language as 'typewritten conversation': a language that is oral conceptually, but medially written. The notion of conceptual is taken here as referring to a prototypical association of the communicative situation and a set of perceptions of situation and register; the theoretical question of whether there are just two, or perhaps three conceptual language media, each prototypically associated with a language medium, will have to be decided empirically. To settle this issue, further empirical research on other languages, as well as on what does NOT occur in Internet language, will be needed.

Pragmatics

The issue of conceptually new media, broached in the previous section, is related to another issue, *viz.* the question to what extent the new Internet genres are simply medial translations of older genres belonging to the traditional language medium. Genres are conventionalized packages, containing as their ingredients communicative purpose, communicative situation, and language register; most of these are tied to one specific language medium (*see Genre and Genre Analysis; Register: Overview*). While it is clear that one significant aspect of language change affected by the Internet is the rise of new genres, this shift is more obvious in some cases than it is in others. MUDs and MOOs, new groups and listservs are clear cases of

new genres in a new language medium; among the unclear cases, the most debated is that of chat.

At issue is the question to what extent spoken conversation is able to preserve its identity in the context of Internet chat. The most obvious common feature for both normal conversation and Internet chat is that of turn taking (*see Conversation Analysis*). Even so, we observe features of the chat that militate against a simple transposition of conversation from one medium to another: for instance, the notion of a turn is defined rather differently in the Internet medium, given its technical constraints on length, which has led to the invention of turn-splitting techniques. Also, the notion of the speaker itself is spread out over two contexts: the actual typing and editing context, and the context in which the message appears on the screen of the other communicant. Moreover, the mechanisms for next speaker selection are entirely different in the two media. Further important differences have to do with the notion of topicality, due to the nonadjacent character of corresponding moves, and in general with interactional coherence, which is a very different notion here than the one we are familiar with from spoken conversation with its narrow constraints. Thus, establishing coherence requires much more work on the Internet than it does in spoken conversation; an important aspect of that special effort is the need to furnish a lot of explicit communicative meta-information on the linguistic surface of the chat, making it in fact appear more autonomous, relying less on shared interactionally focused information than is the case for written language. Given these differences, it is an open question whether the media constraints of the Internet allow us to refer to the chat as typed conversation.

Parallel effects of the technical and communicative conditions on Internet language use can be observed on several other levels. An important consequence of the absence of direct monitoring is, in speech act terms, an increased uncertainty about the uptake of speech acts (*see Speech Acts*). On the one hand, this feature of the communicative situation tends to minimize the danger of loss of face (*see Face*), and thus helps explain the socially more forgiving character of the Internet. On the other hand, it also accounts for a higher degree of interactional uncertainty, especially when it comes to interactionally focused actions and referents. As a consequence, the usual conversational maxims are relaxed, or have to be adapted to the specific communicative situation; in particular, given the specific nature of turn-taking and topic management, the notions of relevance and quantity cannot be the same as in spoken conversation (*see Maxims and Flouting; Relevance Theory*).

Another consequence of the relative uncertainty of interactional focusing is the fact that much more referential effort has to be undertaken in terms of the intensional content of expressions; thus, there tends to be less pronominal reference and more reference by full lexemes. This is particularly obvious when the referents are located in topically coherent, but spatially nonadjacent turns. We see the same phenomenon occurring in hypertext: hypertextual organization cannot rely on a sequential reading in any predetermined order. As a consequence, the modular character of hyper- (or in general: meta-) text enforces a much more explicit, self-contained, and autonomous reference, just as do the Internet genres themselves, and much as does written language. It is obvious that the essentially different social obligations incurred by Internet users have given rise to a substantial number of books on Internet 'netiquette,' testifying to the fact that notions of correctness and appropriateness, analogous to those familiar from written and spoken standard varieties and registers, are in the process of formation (*see Register: Overview*).

Varieties and Communities

Another issue on the borderline between linguistics and sociolinguistics that has surfaced in more recent studies on language on the Internet is the role of varieties. Early work was dominated by the idea that written English was to be the standard on the Internet; standard English operated as a vehicle of globalization, to the disadvantage of other languages, and contributed to an ever more progressive leveling of other languages and dialects. Studies of Internet language, apart from occasional references to non-standard forms as marks of orality, were mainly focused on standard languages. While there is still little work being done on the systematic use of non-standard varieties and dialects on the Internet, it is apparent that there are differences between languages, to the extent that some languages allow their users to exploit such varieties and dialects for purposes of maintaining a local identity; for instance, a language like German appears to be much better represented by its dialects on the web than are others, like French. There is, however, far too little data available on this question, and, as already pointed out, the situation is changing very fast, to the quantitative disadvantage of the world's languages.

Recent work (Androutsopoulos and Ziegler, 2003) has not only moved the discussion away from unreflected, folklore-linguistic doomsday predictions of further language decay on the Internet, to a serious analysis of nonstandard forms by studying actually

occurring, nonstandard language, but it has also taken the debates a step further, in the direction of interpreting the changes in terms of code-switching, of interactional processes, and of language-community networks. As an instance, we may consider the situation on the Indian subcontinent, where core membership in an Internet network is associated with Hindi. In another context, chatters on a German local dialect channel select graphic representations of nonstandard spoken forms and nonstandard grammatical features to establish and confirm their respective membership on several levels of Internet communities.

While much research has been devoted to the nature and the internal structure of Net communities on the part of the social sciences, few studies have been done along the lines of a microlinguistic, interactionalist analysis, showing the micro-structure of the group symbolic use of linguistic forms and variants. Such work would describe local variants of global processes, in which ever larger networks of users develop shibboleths to manifest their status as network members, and ultimately as Internet users. In terms of language variety, what emerges here is a special, medially defined linguistic register. The specific varietal architecture of a language determines the extent to which varieties can assume these functions: nonobservance of spelling rules in a language like French, where the standard variety exerts very high normative pressure, carries much higher information value, and thus more symbolic force, than is, for instance, the case in German.

Language Change

Just as the advent of writing and mass literacy had a major impact on language and languages on several levels, new technical and communicational options are expected to evolve new genres, adapted to the new, sooner or later to be conventionalized communicative situations, with new rules for floor use and altered linguistic norms in terms of register and style. The development of such new genres, registers, and individual expressions, along with the attribution of additional functions to the old forms can generally be seen as an evolutionary process in which users adapt language to the new technical and communicative conditions and functions (*see Adaptability in Human-Computer Interaction*). As the network studies referred to above demonstrate, a core mechanism in this process is that of speakers negotiating, in a cooperative process, markers and symbols of language communities on several levels of networks; such markers and symbols then translate into register markers (*see Register: Overview*).

Above, I have discussed the impact of these processes on the ecology of language(s); in addition, there are several other important lines of research dealing with the effects of the Internet on language. Thus, one of the major future research questions will be to what extent the new registers, inasmuch as they represent the new genres linguistically, will show a convergence of register features and markers. Given the advanced technological sophistication of the new language medium, it could be hypothesized that the registers would be more similar across languages than written registers traditionally have been, even taking into account the existence and influence of typological borders. It will also be interesting to see, given the great differences between cultures when it comes to notions of politeness, if any such convergence will extend to floor behavior in terms of pragmatic constraints and politeness rules, and in particular whether one may expect to see modifications of the cooperative principle. The more technical linguistic evidence regarding typological and cultural convergence vs. difference, to the scant extent that it exists at the time of writing, is inconclusive and does not offer support for either position, whether the discussions are couched in linguistic terms or in terms of cultural theory.

There can be no doubt that the Internet, its terminology, and at least some of its formal linguistic apparatus has, in addition to creating a certain spill-over effect onto the other language media, in particular furthered the influence of English. Technical terminology and the language used in communicative institutions such as 'chat' or 'e-mail' have entered the language at large: compare the use of the 'at' sign (@), domain names (.com, .gov., new lexical formations like 'dotcoms'), terms like 'flaming' or 'spam,' or the new word formations starting with 'e-,' such as 'e-mail,' 'e-government,' and so on. While these new forms certainly represent elements of language change, they are mostly confined to a rather local level, and do not change the overall, let alone the typological character of a language. But they do represent language change under another perspective: language contact. From this point of view, the Internet accelerates a trend that has long been observed for English in contact with other, local languages: the rise of contact varieties. It is to be expected that this tendency will pick up even more speed in the future. It will be interesting to see if the language contact mechanisms observed for spoken contact varieties apply in the same way in the communicative conditions of the Internet.

Since the Internet provides the fastest ever channel of social diffusion, and linguistic change on the broader, societal level is dependent on this kind of

contact, the Internet may well accelerate other, ongoing changes on this more general level of societal change. In particular, with respect to the distribution of the language media over its various domains, the new language medium has effected something like a redistribution of the societal functions with respect to the language medium in which they are carried out. Not that written language is directly threatened as to its function and place of functioning: what has happened is that the spectrum of societal functions and types of communication is now being *shared* between three, rather than two, language media. In practical terms, this change means that there is an increase in genres and registers, amounting to an increase in internal differentiation of the repertoire to be learned and taught.

With regard to research on language change and its methodology, the Internet provides some unique opportunities. Thanks to its easy access to 'texts' (technically available as logs on the web), as elements of written-ness in a medium perceived as one of conceptual orality, the Internet provides a rare window of opportunity for monitoring the micro-mechanisms of this evolutionary process, including the social negotiation that takes place along with it, and traces the diffusion of that process through linguistic and social contexts until the language has changed.

Emancipatory Linguistics

I Signorini, State University of Campinas, Campinas, Brazil

© 1998 Elsevier Ltd. All rights reserved.

This article is reproduced from Concise Encyclopedia of Pragmatics (1998)

The term Emancipatory Linguistics may be used to refer to a trans-disciplinary research field paying attention to topics traditionally viewed as a peripheral or completely outside the purview of mainstream orthodox linguistics. The very objective of this research field is to provide insightful contributions to a socially oriented study of language and discourse activities that would be closely attentive to political underpinnings and implications of linguistic enquiry. This means that since emancipatory linguistics is a term that covers a multitude of rather different approaches, across different disciplines in Language Studies (Discourse Analysis, Sociolinguistics, Socio-pragmatics, Applied Linguistics, Anthropological Linguistics), its distinctiveness lies in its commitment to construct a

comprehensive theory of discursive processes that will provide the basis for political action and emancipatory social change, i.e. for an effective practice of intervention and a relevant concern in linguistic education. Its principal challenge lies in showing how language shapes and is shaped by micro- and macro-political processes, both inextricable and mutually informing language use.

By contrast with a well-established tradition in theoretical and descriptive linguistics, this issue takes language and language users in their concrete sense, rather than in their generic or abstract sense (the Chomskyan "ideal speaker-listener in a completely homogeneous speech-community" (Chomsky, 1965: 3)). As a result, it adopts a critical perspective on linguistic theoretical models that obscure the heterogeneity of the real conditions of the communicative use of language and the relations of language use to the (re)production of the struggle between social forces at the level of private and public interactions. Such critical perspective also devotes serious attention to the social nexus

of scientific practices and assumptions. This article first deals with key analytical concepts that drive research in this field, contrasting them with the epistemological bedrock that informs more conventional research. Secondly, some directions in future research agenda are considered.

Verbal Interaction: From Equality and Cooperation Between Autonomous Subjects to Inequalities, Opaqueness and Irreducible Tensions Between Social Actors

Within the broader framework of a sociolinguistic model for communicative interaction, the introduction of the socio-interactionist perspective of construction/reproduction of social reality through language has made that traditional sociolinguistic categories, such as social identity (gender, age, social class) and ethnicity are no longer understood as abstract a priori categories which have a deterministic effect on the interactional process; rather, they are understood as dynamic, contextual aspects which are ongoing and locally (re)produced, and particularly related to social power, i.e. hierarchized structures of social relations that are constitutive of communication and will circumscribe the possibilities of action available to interactants.

Consequently, instead of the transparency and neutrality of language as an instrument for mediating meaning, presupposed in conventional linguistic models of ideal verbal communication such as the transparent and neutral negotiation between social partners (Grice, Goffman), and in the specific case of democratic deliberation, between enlightened peers (Habermas), what one has is gradual shades of opaqueness and strategic ambiguity of actions mediated by various kinds of cross-cutting sets of social structures which embed and embody social clashes of a cultural, ideological and political nature. This anti-idealist conception of verbal interaction does not characterize misunderstanding and incomprehension as a deviation from the ideal of openness, honesty and clarity, but rather as a norm, since the notions of cooperation, openness and sharing are of an ideological nature, probably originating in Western white society.

In fact, a central claim of this research is that since such tensions and inequalities in verbal communication are symptomatic of and conducive to tensions and inequalities in the broader social reality, there is no necessary and self-evident connection between communicative and social order. Closely linked to such idea of an interdependent non deterministic relationship between micro- and macro-contextual order is the idea of linguistic ideologies as a dialectical mediation link between verbal activities and social structures.

Linguistic Ideologies and Indexicality

Drawing upon but moving beyond the traditional socio-ethnolinguistic concept of context in human language behavior, attention is paid to the very assumption that interpretation is socio-historically situated and ideologically biased. Although the term ideology has a spectrum of competing understandings, this perspective emphasizes the ideological as inherently indexical and plural phenomena that is infused with semiotic processes mediating social life. Recent studies of discourse in institutional settings and in the public arena have explored both the empirical and the theoretical contributions that opens up for an investigation of the mechanisms through which language ideologies index the intersection of different sociopolitical interests.

In the words of Silverstein, through indexicality “signs point to a presupposed context in which they occur (i.e., have occurred) or to an entailed potential context in which they occur (i.e., will have occurred)” (1992: 315), metapragmatically mediated by linguistic ideology, i.e. social and experiential rooted conceptions and evaluations of the relationship between language and cognition, language and power, language and legitimacy, formal and functional devices. Attention to linguistic ideologies and indexicality as embodied and embedded in discourse processes problematizes the oppositions created by the traditional linguistic studies such as those between ideology and science, and between ideology and theory.

Future Research Agenda

With respect to the goal of critical intervention, future research in emancipatory linguistics will discuss traditional reductionist explanatory notions, such as the notion of history and the notion of social structure. Moving beyond the Marxist tradition, such research will interpellate in a more comprehensive way, the complex hierarchical and cross-cutting sets of mechanisms and rationales that drive the micro- and macro-contextual order.

Endangered Languages

L Grenoble, Dartmouth College, Hanover, NH, USA

© 2006 Elsevier Ltd. All rights reserved.

Language Endangerment

Although it is somewhat difficult to count languages and to measure linguistic diversity with exact precision, there are an estimated 6800 languages spoken in the world today. While there is some question as to exactly how many languages will be lost over the course of this century – ranging from a low of 25% to a high of 90% – there is widespread agreement that language loss is occurring at an unprecedented rate. Most recent studies have concluded that at least 50% of the world's languages are losing speakers and that by the end of this century, a full 90% of the world's languages will disappear entirely, replaced by more widely used (national and/or global) languages. This situation is generally referred to as language endangerment, a term used broadly for languages which are threatened with absolute loss; a language is considered lost when it has no speakers. Language endangerment is sometimes called language attrition or language death, but 'death' is avoided out of sensitivity to the population whose language has been lost. Language attrition and moribundity – when children cease learning a language – are now taking place with exceptionally rapid speed. Hundreds of languages are currently endangered and there are few parts of the world where some form of language decline is not occurring. While language attrition is not in and of itself a new phenomenon, the rate of decline in linguistic diversity appears to be unique to this era, and is perhaps rivaled only by the kind of language loss which took place in conjunction with the agricultural revolution of approximately 10 000 years ago. One consequence is that a significant number of communities are facing the loss of a language which historically and traditionally has been foundational to their sense of identity. In some instances communities are reacting with efforts to revitalize the local language, while in others they lack the resources, time, or motivation to do so.

Linguists are particularly concerned with the loss of indigenous, or local, languages, as opposed to immigrant languages. For the latter, the language may give way in the new territory to an already established (national or dominant) language, but a robust speaker community continues/thrives in the homeland of the immigrants. (This is the situation of most immigrant languages in the United States, for example; for the most part, second-generation immigrants speak and use English in their daily lives, but their ancestral language is maintained in their original homeland. English, in contrast, is an immigrant language to North America; for a range of historical, socio-economic, and political reasons, it has largely ousted Native American local languages.) It is the loss of such local languages which is of concern to linguists, as their loss means an absolute kind of disappearance of the language. Thus, by and large, the term 'language endangerment' refers to the attrition and potential loss of local languages. A language is considered endangered when it is used by fewer speakers and when it is used in fewer situations or domains.

Language endangerment typically involves language contact situations, with two (or more) languages in use, where one language (Language A) replaces another (Language B). Prototypically, Language A is being adopted by speakers of Language B and so Language A replaces Language B in the sense that decreasing numbers of speakers of Language B use it, until ultimately there are no speakers of Language B at all. This is referred to as language shift, a term which refers specifically to such changes in patterns of language use, whereby speakers abandon the language of their parents in favor of another language. In the scenario outlined here, Language A can most neutrally be referred to as a language of wider communication; it tends to be a language which holds social prestige, serves official and governmental functions, and is used in education. It is often a regional or national lingua franca, i.e., the language which groups speaking different languages use to communicate with one another. It is also called, less neutrally, the

dominant language, the majority language, or even the killer language. 'Dominant language' is to be avoided as it implies a deliberation on the part of the speakers of that language to dominate others; in some instances this is in fact the case, as when language policies intentionally restrict use of a local language. But in other situations the influence of the language of wider communication is more indirectly and subtly attained, through prestige and social pressures. Similarly, a number of labels are used to refer to Language B, such as minority language, indigenous language, mother tongue, or heritage language. The term 'local language' is more neutral and captures the fact that language use is tied to a particular geography, and that a speaker community generally sees the need or desire to use this language within a given region. The respective terms 'majority' and 'minority' for Languages A and B are not always accurate; speakers of Language B may be numerically greater but in a disadvantaged social or economic position which makes the use of the language of wider communication attractive. The term 'heritage language' can be confusing, as it is often used to refer to the language of one's ancestors, regardless of how many generations have passed since anyone spoke the language. It does not necessarily refer to a local or indigenous language, and can also refer to the ancestral languages of immigrants, even when they have not been spoken for generations.

Predications of language loss stem from several considerations, which center around a combination of critical factors in language vitality, including the number and generations of speakers, their geographic distribution and relative isolation, and recognition of ongoing rapid language shift. First, there is a very uneven distribution between languages and speakers, with just a handful of languages spoken by a very large percentage of the global population. According to current counts, approximately half the world's population speaks one of just 20 languages, and eight languages (Mandarin [Mandarin Chinese], Spanish, English, Bengali, Hindi, Portuguese, Russian, and Japanese) surpass all others with over 100 million speakers. Arabic could perhaps be added to this list: the sum total of all speakers of some form of Arabic makes it the fifth largest language, with over 200 million speakers. Not all varieties of Arabic are mutually intelligible, however, and so the differences between them are more language-like than dialect-like. Yet given the total number of people who speak some variety of Arabic, it should be included in the list of major world languages. The situation is markedly different for most of the world's languages. Some 96% of all languages are spoken by just 4% of the

population, and one-fourth of the total number of languages have fewer than 1000 speakers. More than half of all languages have fewer than 10 000 speakers. Although the total number of speakers is not the sole indicator of language vitality, it is certainly a very important one. A very large majority of the world's population speaks just a very few languages. More to the point is the fact that we are witnessing rapid language shift, with a small set of major or global languages gaining in terms of numbers of speakers at the expense of a vast majority of the world's languages.

Finally, it is important to note that the geographic distribution of languages is also very uneven, with the largest numbers of languages spoken in Africa and Asia, and much smaller numbers elsewhere, such as in North and South America and the Pacific. Europe has a very few languages, both in terms of raw numbers and of percentage relative to the whole. This distribution is summarized in **Table 1**.

Distribution by continent or region is only part of the story. Language density, or the number of languages per unit area, varies greatly. Papua New Guinea stands out with 820 languages; with its relatively small territory, it has the highest language density of any country in the world. In all of North America, fewer than 200 indigenous languages remain, although there were certainly hundreds of distinct languages several centuries ago. Today, only a handful of these (such as Cree, Dakota, Ojibwa, Navajo) have a hope of survival, and even their longevity is doubtful. The case of Cree is illustrative. As of the 1998 Canadian census, there was a total of 87 555 speakers of all varieties of Cree. These speakers are not monolingual, however, and they show low literacy rates in Cree (only 5–10%) but high literacy rates in a second language, usually English (75–100%). Such figures are indicative of significant language shift. The figures for Dakota are even more alarming, with fewer than 27 000 speakers in North America as a whole, and only 31 monolingual speakers (as of 1990). Basic descriptions

Table 1 Geographic distribution of languages

	<i>Total living languages</i>	<i>Percentage</i>
The Americas	1013	15%
Africa	2058	30%
Europe	230	3%
Asia	2197	32%
The Pacific	1311	19%
Total	6809

of Dakota speech patterns note that in some communities the children and young adults do not speak Dakota or at least prefer to speak English. Again, these are all signs of ongoing and advanced language shift, leading toward language extinction.

As this may suggest, in only a very few cases is language loss due to the loss of the speaker population itself. Instead, the primary cause for language loss is language shift, when speakers cease to speak their own native tongue, the local language, in favor of the language of what is usually, politically and/or economically, the dominant culture. Such shift from the local to the language of wider communication can occur over several generations, or even as quickly as over the course of a single generation. In many cases the oldest generation – the grandparent group – speaks the local language as their first and primary language and has limited or nonfluent knowledge of the external language of communication; in some instances they may even have no knowledge at all of the language of wider communication. In contrast, the middle generation has some knowledge but primarily uses the language of wider communication, and the youngest generation has little to no knowledge of the local language, using at best a few words or phrases, such as greetings. In cases of rapid language shift, however, these changes occur across a single generation.

Levels of Language Endangerment

Implicit to the study of language endangerment is the notion that a relatively vital language can change to a state of endangerment at some point, usually when children cease learning the language. In studying language endangerment, it is important to assess degrees of vitality versus endangerment. That said, because a large number of factors enter into each situation, it can be difficult to rank levels of endangerment. Therefore, different linguists have proposed a variety of scales, with differing numbers of stages of endangerment and different labels for each level. There is, however, widespread agreement on the ends of the scale: safe languages and extinct languages. Generally, languages are categorized with respect to endangerment on a scale of six levels: safe, at risk, disappearing, moribund, nearly extinct and extinct.

Safe: A language is considered safe when all generations use the language in all or nearly all domains. It has a large speaker base relative to others spoken in the same region and, therefore, typically functions as the language of government, education, and commerce. Many safe languages enjoy official status

within nation-states, and as such tend to be held in higher prestige than other languages.

At Risk: A language is at risk when it is vital (being learned and used by people of all different age groups) without any observable pattern of a shrinking speaker base, but lacks some of the properties of a safe language: for example, it is spoken in a limited number of domains or has a smaller number of speakers than other languages in the same region.

Disappearing: A language is disappearing when there is an observable shift towards another language in the communities where it is spoken. With an overall decreasing proportion of intergenerational transfer, the speaker base shrinks because it is not being replenished. Disappearing languages are consequently used in a more restricted set of domains, and a language of wider communication begins to replace it in a greater percentage of homes.

Moribund: A moribund language is one that is not being transmitted to children.

Nearly Extinct: A language can be considered nearly extinct when only a handful of speakers of the oldest generation remain.

Extinct: An extinct language is one with no remaining speakers.

It should be noted that sometimes an intermediate stage between 'safe' and 'at risk' is recognized, 'safe but small,' determined by languages which are otherwise safe and stable but have a relatively small speaker base. The last three levels of language endangerment given here – moribund, nearly extinct, and extinct – are characterized by a lack of intergenerational transmission; disappearing languages are characterized by a downward trend.

Many linguists would argue that any language which is not at the safe level is endangered. Furthermore, there does not appear to be a direct correlation between the level of endangerment and the anticipated rate of language attrition: some communities shift language usage more slowly, and others more quickly. That said, language endangerment is currently a pressing concern for the linguistic community precisely because rapid attrition is occurring at a global level. In addition, the kinds of documentation and revitalization efforts needed are directly related to the level of endangerment. The closer a language is to extinction, the greater the urgency to act before fluent speakers are gone. Except in cases of sudden attrition (e.g., when a language is abruptly lost through natural catastrophe or warfare; see the next section), endangered language situations tend to be characterized by speakers of differing proficiency levels. Languages ranked at any level below safe

tend to have communities which include individuals who are semispeakers, i.e., not fully fluent speakers, lacking native proficiency; the ratio of semispeakers to fluent speakers varies among communities and with endangerment levels. Such semispeakers show varying degrees of fluency, ranging from strong or nearly fluent speakers, through reasonably fluent semispeakers and weak semispeakers who are less fluent, to those with even more limited speaking competence. In assessing language vitality, it is thus important to take into consideration the proficiency and knowledge of the speakers of the language. Even in the case of extinct languages, there may be cause to move quickly, as there may still be ‘rememberers’ of the language who have some recollection of its use or may have some experience with it. Sometimes communities opt to resurrect (or ‘resuscitate’) extinct languages; rememberers can play a critical role in these efforts. Here too there is a range of proficiency: in some cases such rememberers have memorized entire texts without understanding their meaning, while the knowledge of others is restricted to only a few words or phrases. Rememberers can play an important role in language revitalization and documentation efforts, but they are static and do not represent living language.

What Is Lost?

There are a number of reasons to be concerned about language attrition. Language is a key part of each person’s identity and is an essential component of a group’s cultural and social heritage. Local communities who have lost their language speak about it as a deeply personal loss which is accompanied by a loss of a sense of self. Speakers whose languages are not endangered are also aware of the importance of language as a marker of identity and pay great attention to differences in dialects and speech patterns. Thus perhaps one of the most compelling reasons to be concerned about language endangerment is that the speakers who lost this part of their heritage deeply regret it and grieve over it. For this reason, so many different communities around the world are currently engaged in language revitalization efforts. Some of those groups whose languages are extinct are now attempting to resurrect them from whatever records have survived, including missionary descriptions, grammars, and sometimes oral recordings.

Loss of language also means a loss of intellectual wealth. From the linguistic standpoint, as we lose languages, we lose linguistic diversity. A great many of the world’s broad array of endangered languages are understudied; what little knowledge we have indicates that many are structurally very different from

the languages spoken by the majority of the global population (e.g., Mandarin, English, Spanish, and so on). The languages with the most speakers, cited in **Table 1**, represent a very small portion of the world’s languages typologically and genetically. Thus language loss means a decline in sources about the range of human language and its limitations. For the linguistic community, one of the challenges of language endangerment is to record and describe as many languages as possible while they are still spoken, so that we do not lose this wealth of human knowledge without record. Language loss should also be considered from the broader scientific perspective. Language encodes the range of human experience and knowledge; its disappearance entails the loss of the skills, information, beliefs, and ideas of a people. Often this involves specific knowledge about plants and their medicinal uses. It also includes historical knowledge; preliterate societies record their histories in their oral traditions, including stories, legends, and songs which tell the history of their people, settlements, battles, and so on. Language is more than a repository for religious and spiritual beliefs; in many societies the language itself is sacred and cannot be separated from religious beliefs and practices.

Taxonomy of Endangerment Situations

Language change and loss are naturally occurring processes which have been in place as long as language itself. Every language is constantly changing over time, and eventually evolves into one or more related but different languages; for example, the modern Romance languages (Spanish, Italian, French, and so on) are related to Latin, which is no longer used as a spoken language except for religious purposes. This kind of language ‘loss’ is a natural and ongoing process. Linguists are more concerned, however, with the absolute loss of language, which occurs when a language disappears entirely, without descendant languages. This kind of loss comes about in several different ways. Sometimes an entire speaker community passes away due to warfare, genocide, or disease. More frequently, however, language loss is the result of language shift, when speakers cease to speak their own native (local) tongue in favor of the language of what is usually the dominant culture, dominant politically and/or economically. The time frame for such shift varies across situations; it can take place over several generations, or much more quickly. One typical pattern is that the oldest generation, the grandparents, speaks the local language as their first and primary language, the middle generation has some knowledge but uses the dominant language primarily, and the youngest generation has little or no

knowledge of the heritage language, and may at most know a few words or phrases. In cases of rapid language shift, however, these changes occur across a single generation, with the parent generation speaking the local language but their children, for whatever reasons, speaking a different one.

There are a number of ways to categorize language endangerment situations. One useful taxonomy takes into account the relative rate of attrition together with its causes. This taxonomy recognizes four different categories of attrition: sudden, radical, gradual, and top to bottom.

Sudden attrition refers to language loss which occurs abruptly because of the sudden loss of its speakers due to disease, war, natural disasters, and so on. Relatively few cases of sudden attrition have been documented, although it most probably occurred more frequently during periods of colonization, when certain indigenous groups are known to have been annihilated due to disease. In modern times, civil strife, ethnic and religious clashes, and the spread of some diseases, such as HIV, increase the chances of sudden attrition occurring in certain areas of the world.

Radical attrition is similar to sudden attrition in the sense that it comes about due to political circumstances which cause speakers to stop using their language. Such circumstances include repression and/or genocide, often occurring where groups are singled out for ethnic cleansing. (Under colonization and later, apartheid in South Africa, for example, Khoisan speakers abandoned their ethnic identity and so too their languages in order to avoid repressive measures which included genocide.) Such language shift is thus a means of self-defense or even self-preservation for speakers for whom identification with their ethnic group may lead to persecution. In these circumstances people are likely to cease speaking their heritage language abruptly.

Cases of gradual attrition are more prevalent in the world today. Gradual attrition is the relatively slow loss of a language due to language shift away from the local language to a language of wider communication. In some cases the language of wider communication is a regionally dominant language, and in others a national lingua franca. Gradual attrition often involves transitional bilingualism: as the speaker population is in the process of shift, certain groups primarily speak the local language and others the language of wider communication. Thus it is here that the clearest gradations in intergenerational transmission are to be found. Because this type of attrition is gradual, speaker communities may be unaware that it is in progress, until it is quite advanced and the local language is seriously endangered.

Bottom-to-top attrition refers to the loss of the local languages in most domains with the exception of religious and ritual practices. Languages at this level are in an advanced stage of attrition. The local language is preserved only in those contexts where its use is seen to be the most critical. This tends to be those types of context where ritualized or sacred texts are critical, and the population may view the specific language of these as sacred in and of itself. Such ritualized or ceremonial texts are often memorized. Because these tend to be very prestigious but restricted domains for a community, it can be difficult to assess the actual vitality of the language in question. In less advanced instances of bottom-to-top attrition, the language is still used spontaneously in the settings to which it has been assigned by members of the local community. In extreme cases, the only remaining knowledge of a local language may be memorized portions of a ceremony. There are reports of communities which have retained the memorized rituals in the local language for many generations but have lost all comprehension of them.

Assessing Language Vitality

The factors involved in assessing language endangerment or vitality are complex. Language vitality is usually ranked in scalar terms on the basis of a combination of factors, in particular on numbers and generations of speakers. On one end of the scale are extinct languages which are no longer spoken at all, and on the other end are viable languages in no current threat of endangerment. In between these two extremes, a number of stages can be recognized. A healthy language with strong vitality is used with a variety of functions and in a range of settings, usually called domains. The most vital languages are used in all settings, formal and informal, official and in the home. In cases of language attrition, the local language is used in increasingly fewer domains with fewer functions as attrition progresses. Simply put, an important diagnostic in assessing vitality is the range of uses of a particular language.

Although it is often thought that the absolute number of speakers of a language is the key factor in language vitality, experts agree that in fact it is intergenerational transmission which is critical in determining it. In order for a language to be healthy, it needs to be used by future generations. When children cease learning and speaking a language, it is already endangered, even if there still exists a significant number of speakers. Intergenerational transmission does not in and of itself guarantee the safety of a language, however, as a complex set of factors are involved. These all pertain to questions of who uses

the language, how, and when. In 2003 UNESCO's Ad Hoc Expert Group on Endangered Languages established a core set of nine criteria to be used in determining language endangerment:

1. Intergenerational transmission
2. Absolute number of speakers
3. Proportion of speakers within the total population
4. Trends in existing language domains
5. Response to new domains and media
6. Materials for language education and literacy
7. Governmental and institutional attitudes and policies, including official status and use
8. Community members' attitudes toward their own language
9. Amount and quality of documentation.

These nine factors are key in assessing language vitality. Variables (1)–(3) involve the distribution of speakers of the language, relative to the total number of the ethnic population as well as to generational stratification, and in absolute terms as well. Variables (4) and (5) are concerned with domains of language use; (7) and (8) with attitudes at the local and national level; and (6) and (9) are related to the kinds of material available for the language, including both pedagogical and reference materials as well as linguistic documentation. Strictly speaking, the level of linguistic documentation relates to language endangerment only insofar as ample documentation can aid language revitalization or resurrection efforts; the act of documenting a language does not directly affect its vitality.

Intergenerational Transmission

Intergenerational transmission is the single most important factor in determining a language's viability. In order for a language to remain healthy, it must be spoken by children, as they are the representatives and predecessors of future generations of speakers. For this reason, intergenerational transmission is the single most critical factor in a language's ongoing vitality. At the same time, rates of intergenerational transmission may vary between villages or speaker communities and it cannot be assumed to be uniform across a speaker population. There can be variation within a single village: it is often the case that in one family the children do not learn to speak the local language but in another they do. As this accurately suggests, overall language vitality may be uneven, higher in some communities and lower in others. A thorough analysis of language vitality requires attention to such regional variation in addition to the generational variation in transmission and use. A 10-way distinction in terms of transmission and

use is proposed by Krauss (1997) to enable a more detailed means of assessing variation in speaking patterns across generations:

- a. The language is spoken by all generations, including all, or nearly all, of the children.
- a-. The language is learned by all or most children.
- b. The language is spoken by all adults, parental age and up, but learned by few or no children.
- b-. The language is spoken by adults in their 30 s and older but not by younger parents.
- c. The language is spoken only by middle-aged adults and older, in their 40 s and up.
- c-. All speakers are in their 50 s and older.
- d. All speakers are in their 60 s and older.
- d. All speakers are in their 70 s and older.
- d-. All speakers are in their 70 s and older, and there are fewer than 10 of them.
- e. The language is extinct, with no speakers.

As this scale suggests, it is important to make distinctions across age-groups within a single generation as well as across generations. Some might argue that a language is already in danger at stage (a-), when some of the children are not learning it. At stage (b), there is a greater level of danger, and so on; if the language is to survive at this stage, efforts need to be made at revitalization, or for reversing language shift. This scale may appear overly detailed; it is clear that a language is already on the way to extinction when it has reached stage (b). Yet at times it is needed. First, it can be quite useful in assessing the relative vitality not only of different languages, but at times more importantly, of various speaker communities. Inuktitut, for example, can be rated at level (a) in Greenland, where there are fluent speakers of all generations. (There are other factors which enter into its vitality in Greenland, such as official language status and use in education.) In some other Inuktitut-speaking communities, however, children are not learning the language and it is on the path to extinction. This is the case in specific communities in Canada and Alaska, although the children are acquiring it in other communities. This example further underscores the fact that evaluating the overall status of a language can be difficult, as it may vary from community to community. Second, if community members decide to revitalize their language, it is important to have an accurate understanding of the ages and numbers of fluent speakers who can assist in the revitalization effort.

Absolute Numbers of Speakers

Absolute population size alone is not a definitive indicator of language vitality. Each individual

community is embedded in a set of circumstances that affect language use, so that even a small isolated rural community which has little contact with speakers of other languages and in which all members, of all generations, learn and use the local language, cannot reasonably be called endangered. That said, as a general rule, the more speakers, the more likely the community will be able to resist language shift. Put differently, small communities are at greater risk, because they can more easily disappear due to any one of a number of natural or man-made catastrophes. Furthermore, a small community can more easily be assimilated to a large community, and is likely to have fewer resources to resist external pressures. Yet small size alone does not condemn a language to extinction, because the nexus of relevant factors may actually favor language use. A case in point is Icelandic. It is spoken as the first language by a relatively small group of people (approximately 300 000), but it is the national language of the country of Iceland, has a long-standing literary history, and is a language of education. Icelanders have a strong sense of pride in their cultural and linguistic heritage and teach Icelandic to their children as their first language. It is hard to characterize it as being in any way endangered. By the same token, a relatively large speaker community does not guarantee language vitality. Navajo, an Athapaskan language spoken in North America, provides an example. Although there are currently approximately 178 000 speakers (2000 census), there is ample evidence of advanced language shift. In 1968, a full 90% of first-grade children spoke Navajo as their first and primary language; by 1990 this figure had dropped to 30%. Despite the relatively large speaker base, it is doubtful that future generations will speak Navajo unless measures are undertaken to assure its continuance.

Proportion of Speakers within the Total Population

The ratio of speakers of the local language with respect to the total population of the local community is an important diagnostic in evaluating language vitality. For safe languages, all of the population speaks the language. In contrast, for extinct languages, none of the population does. In between these two extremes, languages can range from unsafe, with early language shift, where nearly all of the population still uses them, to severely endangered, where only a small percentage do. The larger the percentage speaking and using the language in an active way, on a daily basis, the more likely the language is to maintain its vitality.

In addition to the ratio of speakers of the local language to the number of people who would

claim that local language as ancestral, it is useful to compare how the local language speakers are embedded in a larger social and cultural context. Often local communities are in a minority position with regard to a national culture, represented by speakers of a language of wider communication. The narrower the gap, the stronger the position of the local language.

Trends in Existing Language Domains

A vital language continues to be used in existing domains, while in contrast an endangered language is used in fewer domains. The differences in usage can be placed on a continuum, with safe languages used in all domains for all purposes. Next are situations of what is called diglossia, or the use of different varieties in different contexts. Here a language of wider communication, usually a regional or national language, is the one used in official domains, such as government, education, and other public offices and institutions. The local language, in contrast, is also used in public domains, including not only traditional (local) places of worship or other religious institutions, but elsewhere as well. Typically, the local language is used in the home and informal domains, and the language of wider communication in official domains, and both can be used in public domains. Older members of the community may use only the local language. Next on the continuum is what the UNESCO Ad Hoc Group of Experts terms dwindling domains, when use of the language of wider communication spreads at the expense of the local language. The critical change here is that the local language is used less frequently in the home and is not transmitted to children. This state is further characterized by bilingualism in both the parent and grandparent generations; the children tend to be semispeakers but may be bilingual if the local language is spoken in the home. As this description suggests, at this point there is advanced language shift; the language is endangered and could be ranked as disappearing or even moribund. There are two final stages in this continuum which precede extinction: limited or formal domains is one, and highly limited domains the other. The former is characterized by use of the local language at festivals and ceremonies, in particular when the older generation is present (and therefore using the language). Often the use of the local language is itself tied to the rituals of these occasions and to an extent may be formulaic in usage. UNESCO also includes use of the language in the home in this category when such use is limited to the grandparent generation. The next stage, highly limited domains, represents even greater restriction

in use of the local language. It is used only by a very small number of people on very particular occasions, and its use is often ceremonial.

As is clear from this description, the range of domains in which a language is used can be correlated to the generational distribution of speakers and their levels of proficiency. Use in all domains requires fluent speakers of all ages. Loss of intergenerational transmission, by its very definition, is indicative of a restriction in domains, as it signals that the language is not spoken in the home setting with children.

Response to New Domains and Media

Vital, safe languages are not only used in existing domains, but a measure of their strength is the extent to which their use is extended to new domains. These are created as society and conditions change, and an important measure of a language's vitality is the extent to which it evolves with the people who speak it. The general pattern, worldwide, is for the language of wider communication to be used in emerging domains, including formal education and media of all kinds. The question of language use in the media is critical. The media helps spread language use and fosters its growth and/or maintenance. Moreover, use of a language in media is an important indication of that language's prestige and the kind of support it receives from the larger (dominant) culture, the allocation of resources, and so on. Finally, the media represents prestige and affluence, and the language used in the media is associated with both of these.

Education is a key domain for language use. By its very nature, education promotes the language of instruction and fosters its use. Many local languages are not used in schools; in places where they are, they are more likely to be taught as a secondary subject and not used as languages of instruction. For a language to be truly vital, not only must it be taught in the schools, but it also must be used to teach other subjects.

Materials for Language Education and Literacy

Most linguists and local community members agree that education and literacy in the local language are necessary to maintain vitality, or to revitalize a language threatened with endangerment. Some local communities reject this notion, wanting to preserve their oral traditions and to rely solely on them. There is, however, a cost to this decision, as it limits the domains in which the language can be used. Regardless, most regard literacy as essential for local languages. Yet more than half of all languages have no written form, and so a writing system needs to be developed for them in order to use them in education

and literacy programs. Basic pedagogical and reference materials are needed, including textbooks, dictionaries and usable descriptive grammars. Such materials are readily available for languages of wider communication, but not for the majority of local languages. In addition, reading material is needed for literacy as well.

The existence and use of such materials is another diagnostic for assessing language vitality. UNESCO uses a scale of six levels in this assessment; each of these levels correlates with ever-decreasing vitality. At one end, safe and stable languages have an established orthography with a written tradition that includes a full range of written materials; the language is used in official domains such as government and education. At the next level, the materials exist and are used by children in the school, at least in terms of developing local language literacy, but the written language is not used in the government or administration. At the third level, children are exposed to written materials in the schools; they may play a role in education but print media, such as newspapers, journals, magazines, do not use the written form of the language. At the next level, although written materials exist, they are not used in education. Only some community members use them, while for others, their existence may have symbolic value. At the fifth level, the community has knowledge of a writing system and some written materials exist. Finally, at the other end of the community, there is no orthography and the language has no written form.

The singular importance of literacy, as presented by the UNESCO Ad Hoc Group of Experts, is not one which would be embraced by all linguists and by all community activists. It represents a practical view of the role of writing and literacy in the modern world in which local languages compete to survive.

Governmental and Institutional Attitudes and Policies

National and regional governmental policies, laws, and attitudes all play a critical role in the fate of local languages. Policies can be viewed as supportive, fostering the use and development of local languages. They can be benign, not explicitly supportive but also not disadvantageous to local languages. Governmental policies can also be explicitly hostile toward local languages and can actively discourage their use.

There is a direct relation between national-level policies and the attitudes of speakers of the language of wider communication. Positive policies at the national level tend to reflect the overall attitudes of the population toward local languages. One aspect

of this is attitudes toward bi- or multilingualism. While some nation-states (such as Canada, Nigeria, or Switzerland) are multilingual, with multiple national and/or official languages, others (such as the United States) are unequivocally monolingual at a national level with regard to language and education policy, as such policies are intended to promote the use of one and only one official language (English, in this case). Because the use of local languages almost always entails at least bilingualism to some degree, so that community members can function at local, regional, and national levels, these languages suffer in countries which are dogmatically monolingual.

National-level attitudes can influence local attitudes. Language is closely associated with the people who speak it; negative attitudes toward a specific language translate into negative thoughts and beliefs about the speakers and their culture, social norms, and heritage. Such negative views can further influence the views community members have of their language. They may perceive it as backward, useless, underdeveloped, and so on, or they may see it as an impediment to advancement in a larger society which does not value their specific local language. Needless to say, such attitudes have an adverse effect on language use and foster language attrition. The role of community members' attitudes toward their own local language cannot be overstated. Where there is a strong sense of pride in the language, it is more likely to be used and less likely to move into an endangerment situation. In cases where language attrition has begun, the chances of reversing language shift are considerably greater if the people have positive attitudes toward the local language. In the absence of these, a revitalization program must begin by fostering community support.

Causes of Language Shift

The precise causes of language shift are specific to each individual endangerment situation, yet several key factors often come into play. These include urbanization, globalization, and what have been called social dislocation and cultural dislocation. Often the causes of language shift center around imbalances in prestige and power between the local language and culture on the one hand, and the language of wider communication and dominant culture(s) on the other. The imbalance, or unequal levels of power, often means that members of the local community are socially disadvantaged in a number of ways with respect to the majority population. In concrete terms, this frequently means that members of the local community are relatively powerless politically, and are less educated and less wealthy, in many cases living

in poverty, and with less access to technology and modern conveniences, than the majority population. One common result is that this socially disadvantaged position becomes associated with, or even equated with, the local language and culture, and so knowledge of the local language is seen as an impediment to social and economic advancement. Socio-economic improvement is thus perceived as tied to knowledge of the language of wider communication, as is renunciation of the local language and culture; for this reason, the situation has been called social dislocation. Social dislocation stemming from lack of prestige and power is one of the most powerful motivating factors in language shift.

Related to social dislocation is what has been called cultural dislocation, which comes about as a result of modernization and globalization. These two related forces bring people from different cultures, speaking different languages, together in a variety of settings, from informal to official, including religious and educational settings. This often results in the culture of the minority giving way to that of the majority. At an extreme, globalization is feared to lead to cultural homogenization. The loss of cultural distinctions supports a loss of linguistic distinctions, since the culture is embedded in the language.

Urbanization is another key cause of language shift and is itself related to cultural and social dislocation. Urbanization brings people from different regions and cultures into the same living and working spaces. They are necessarily required to communicate with one another and so turn to an established *lingua franca* or language of wider communication. It is not surprising that we find the highest levels of language retention in rural areas; in general, the more isolated a community, the more likely it is to maintain use of the local language. Urbanization has the opposite effect: by bringing people into contact, it facilitates language shift.

Globalization puts even greater pressure on local languages and can be a major factor in language shift. One of the results of globalization is the emergence of at least one global language of wider communication. A global language is a particular type of language of wider communication, and in some instances may supplant the national language in this role. The global nature of trade and commerce has in recent decades put increasing pressure on the need for an international *lingua franca*, a position currently held by English. Whereas historically it was important for key figures in world politics to be able to communicate, it is now critical that a large number of people in all walks of manufacturing and business communicate with one another, increasing the need for a global language. Some local communities thus see

the knowledge of a global language as necessary for socio-economic advancement. In cases where knowledge of a national or regional language is also important, and in fact may be the only language of education, the need to know the global language can supplant the need or desire to know the local language.

Thus in the modern world, multilingualism generally involves knowledge of one or more national languages and, increasingly, of the global language. This represents a change in traditional patterns, when speakers knew a number of local languages. The shift stems from a combination of factors including education, social prestige, and socio-economics. One factor which has led to diminished local-level multilingualism is the current importance of the national language in terms of access to education, higher-paying jobs, the media, and social advancement. The national language provides a language of wider communication which makes knowledge of multiple local languages less necessary. A key characteristic of language endangerment is that use of the local language is limited, not only regionally but also functionally. In some cases, it is used only in the home, while in others, it is used in the village but not for communication with people living outside of the immediate community, and so on. Thus, the uses of the local language have become increasingly limited, with the net result that it is increasingly important for speakers to learn not only a language of wider communication but also, in many instances, a global language.

Strengthening Language Vitality

A number of steps can be taken to strengthen language vitality and reverse language shift. These require action and commitment on the part of community members and at the level of national government alike. Such steps include instituting educational programs which teach and promote use of the local language, and establishing national language policies which make these possible and which support linguistic diversity. An often critical part of such programs is the development of literacy in the local language. In most cases, pedagogical materials need to be developed and teachers need to be trained; in cases of advanced attrition, they will need to be taught the language itself, in addition to language pedagogy.

As this implies, levels of extinction and degrees of fluency (especially among semispeakers) are of great relevance to language revitalization efforts. Disappearing languages often have fluent speakers of many ages who can be enlisted in the work of revitalization. For moribund or nearly extinct languages,

this is considerably less likely, and the importance of semispeakers to the ultimate success of the process grows considerably. An extinct language may still have rememberers who, although they have no active speaking ability, may know individual words or phrases, such as greetings. So even in cases of extinction there may be a variety of levels of lingering knowledge.

Environment and Language

P Mühlhäusler, University of Adelaide, Adelaide, Australia

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The notion of environment, like that of language, is a complex one, and there are a number of views on the most appropriate approach to this topic. The title of this article suggests that they can be treated as independent entities and correlated to one another. Moreover, it suggests that language is central, and that the environment surrounds this center. This implies that the principal task of the investigator is to look for significant correlations between the two. The correlational approach contrasts with the view that languages are integrated with their environment and that correlations therefore are not of central concern.

Whenever the coverage of a discipline such as linguistics is extended, problems of definition arise. I comment here on the notion of 'environment of language' first and turn to attempts to define 'language' in the next section.

Environment of language has been characterized differently by different writers. Sapir (1912: 227) distinguishes between physical and social environment but cautions that:

The mere existence, for instance, of a certain type of animal in the physical environment of a people does not suffice to give rise to a linguistic symbol referring to it. It is necessary that the animal be known by the members of the group in common and that they have some interest, however slight, in it before the language of the community is called upon to make reference to this particular element of the physical environment. In other

words, so far as language is concerned, all environmental influence reduces at last analysis to the influence of social environment.

One such social influence that has received much attention in recent years is how different social roles of men and women are reflected in gender-specific language and discriminatory language use. Similarly, a number of ecofeminists have argued that man-made language is a root cause not only of social discrimination but also of unhealthy environmental attitudes.

Perhaps the best-known characterization of the environment of language is given by Haugen (1972: 325), who pointed out that the search for an appropriate definition of 'environment' might lead one's thoughts first to the referential world to which language provides an index. However, this is the environment not of the language but of its lexicon and grammar. The true environment of a language is the society that uses it as one of its codes.

Haugen further limits his investigation to the linguistic environment of language (i.e., the users, the relation to other languages, and the agencies concerned with the form and use and attitudes, but not their relationship to the natural environment). Haugen's ideas reflect his experience of Norway, with its competition in colonial days between Danish and Norwegian, and in independent Norway between three competing proposals for a national language. He was furthermore influenced by his experience of migrant languages in the United States, and his observations of language in modern nation states are repeated in many of the pre-1990 writings on this topic (e.g., the contributors to Enninger and Haynes [1984]).

In more recent years, the notion of environment of language has been widened considerably. Fill (1993)

includes parameters such as age and gender into the ecology of language and, in the wake of the growing awareness of a worldwide environmental crisis, the relationship between language and the natural environment has become a focus of research interest. The question of whether environmental problems are in part a consequence of a growing mismatch between the contours of language and the contours of the natural environment has been asked by Mühlhäusler (1983), Trampe (1990), Halliday (1992), and Fill (1993).

There are four logically possible relationships between languages and their environment, all of which have been the subject from time to time of different schools of linguistics: the independency hypothesis (Chomsky, cognitive linguistics), language is constructed by the world (Marr), the world is constructed by language (structuralism and poststructuralism), and language is interconnected with the world – it both constructs and is constructed by it (ecolinguistics).

In the emerging discipline of ecolinguistics (Fill, 1998; Mühlhäusler, 2003), all of these relationships are considered, though the importance of the independency view of language has been greatly reduced.

Linguists continue to differ on the kinds of relationships they regard as most important and on what aspects of the world are perceived as most influential. Regarding relationships, the majority of writers on language and environment continue to emphasize the central role of competition (Haugen, 1972; Mufwene, 2001). The experience of competition between the nation states of Europe seems to be the metaphorical basis for this emphasis, but in numerous traditional societies, small languages have coexisted with larger ones without any danger of them being lost. Ecolinguists such as Fill (1993) note that competition is far less important in nature than commonly believed, and that more than 80 percent of all interactions between natural species are either beneficial or neutral.

The aspects of the world deemed most important by linguists are social factors – contact with other languages and varieties as well as the metalinguistic beliefs and practices prevailing in a language community. The interaction between languages and their natural correlates have remained subsidiary to this, partly because earlier attempts to explore the nature of language with reference to their environments have been fairly crude. The notion that language and environment adapt to one another is recent, and as yet not fully developed, but progress has been made in the study of the relationship between linguistic diversity and the diversity of natural life forms (Nettle, 1999), between conservation, biology and language

conservation (Mühlhäusler, 2003; Harmon, 2002; Maffi, 2001), and between language development and environmental conditions (Mühlhäusler, 1996).

Metaphors and Definitions of Language

The primary purpose of definitions is to create a research tool. The question of a suitable definition of language needs to be distinguished from the question of its ontology – the actual nature of language. Haugen's notion of a 'language ecology,' in which languages interacted with other languages and their environment, was not conceived as a claim about the essential nature of language, and he made it clear that this was not a suggestion that languages are organisms. Language ecology for a long time remained a useful metaphor that helped answer questions such as the disappearance of minor European languages and the causes of language conflict.

Those who use the notion of language ecology metaphorically have held varying views on the nature of language, ranging from that a mental organ to that of a social semiotic. However, ecolinguists, similar to integrational linguists, question the independency view of language and claim that, as language is inextricably linked to wider ecology, its ontology is that of an ecological phenomenon (Finke, 2002; Mühlhäusler, 2003).

Themes in Language and Environment

There are numerous approaches to the relationship between language and environment (surveyed in Mühlhäusler, 2003). I restrict the discussion here to those that start at the linguistic end (i.e., studies focused on the properties of words, grammar, and discourse).

Properties of Words

A focus of many present-day writers is the proliferation of neologisms that have emerged in the wake of growing awareness of the global environmental crisis: Most of the new terms are the result of terminology planning rather than spontaneous innovation, an example being the INFOTERRA Thesaurus (1997). Most of the new terminology originates in English, is highly technical, and consequently abounds in abstract nouns, multiword formation, and words of Latin and Greek origin. The appropriateness of such formations in environmental discourse has been questioned by numerous writers (summarized in Harré *et al.*, 1999), who point out the dangers of substituting greenspeak for environmental action. They have also drawn attention to the trend to introduce deliberately misleading terms to

deflect public attention of problematic practices. Examples of the latter category are 'land reclamation' for wetland drainage, 'sustainable agriculture' for agriculture aimed at sustainability, 'vegetation manipulation' for clear felling, and 'game management' for hunting of wild animals.

Critical ecolinguistics, pioneered by Halliday in 1992, exposes the growthism (portraying growth as semantically unmarked and positive: bigger is better), classism, and speciesism (privileging the human perspective: man is the master of creation) of Western languages, and there are now numerous studies on these trends (see Fill and Mühlhäusler, 2001). The dominance of inappropriate English expressions in the environmental domain is spread through translation. European Union legislation, for instance, requires intertranslatable environmental terminology, and the new member states model their terms on existing English expressions. The resulting process can be characterized as semantic colonization. Conversely, environmental concepts from traditional languages spoken in nonindustrial societies rarely find their way into the green terminology that has developed in English and other world languages over the last decades.

Properties of Grammatical Constructions

Studies beyond the level of green lexicon are rare. Halliday's (1992) suggestion that grammars are the fossilized memory of experience has prompted a number of writers to explore how radically different grammars (e.g., ergative vs. nominative-accusative) reflect fundamentally different attitudes to the relationship between humans and nature. They point out, for instance, that ergative languages, or languages in which cause-effect relationships are difficult to encode, reduce the disposition of their speakers to change their environment. Noun classification systems differentially emphasize or deemphasize the solidarity of humans with other life-forms, as does the inclusion or exclusion of animals in the same gender class as humans.

An extensive list of environmentally problematic grammatical practices in modern European languages is given by Chawla (1991). These practices include passive constructions in environmental texts, which suppress the actor or human agency in environmental degradation, and nominalizations, which reduce processes to abstract objects, as in 'water condenses' becoming 'condensation occurs.'

Properties of Texts and Discourses

The Whorfian idea of linguistic determinism suggests that language structure predisposes language users

to develop specific attitudes and actions. It fails to account for the observation that within one and the same language, very different discourses about environmental matters can be produced. For instance, different language is used by developers and environmentalists to describe the same landscape. These differences involve lexical choice as well as the differential use of pronouns. Thus, 'we' can refer to either 'humans and nature' or 'developers and clients.' Similar differences between conservationists' and seal hunters' discourses have been described by Martin (1986). When examining discourses from a narrative perspective, it is found that groups with opposing views on environmental issues typically use the same narrative structures, the difference being the choice of who are the heroes and who are the villains (see Harré *et al.*, 1999). Very different perceptions of the environment are created by the economic, moral, and scientific macro discourses. These discourses often raise conflicting perceptions, particularly on issues such as the need to reduce overpopulation of animals to prevent destruction of their habitat. Irving (2002) describes the cyclical discourses about the koalas of Kangaroo Island. These animals, which enjoy a charismatic status on the Australian mainland, were introduced to the island in the 1920s, where they multiplied to plague proportions. Scientific arguments for the cull or reduction of the koalas have been repeatedly put forward and rejected on moral and economic grounds, and the matter remains unresolved. Another domain in which scientific discourses clash with economic and moral discourses is ecotourism (Mühlhäusler and Peace, 2001).

Environmental Metaphor

Because environmental awareness is of recent origin in Western societies, environmentalist language not only developed numerous new terms but also developed a number of metaphors. Such metaphors have been the focus of several studies (Harré *et al.*, 1999; Döring, 2002; Mühlhäusler, 2003). Environmental metaphors can be analyzed as cultural core metaphors (e.g., our environment is the book written by God, a larder, or a machine), rhetorical devices that help reconcile conflicting discourses (one buys products that do not cost the earth), heuristic devices (the 'sink' metaphor has been employed to explore the possibility of reducing global warming through heat sinks and carbon sinks), and rhetorical devices to justify environmental policies such as population control (lifeboat earth, spaceship earth).

Those concerned with the effect of key metaphors on environmental perceptions and actions note that the different players in the environmental debate live

by a range of different metaphors. This makes both local and global agreement on environmental action very difficult.

Critiquing environmental metaphors is a key concern of many ecolinguists. Ecofeminists have pointed out that the metaphors of male explorers such as 'virgin territory' or 'penetrating the interior' are essentially rape metaphors. Similarly, managerial, corporate metaphors such as 'environmental management system,' 'environmental auditing,' 'environmental performance evaluation,' or 'environmental objectives' have received much criticism, as has the metaphor of reification, the portrayal of situated processes as timeless, bounded objects.

Ongoing Dichotomies

In what has been said thus far, the notions of language and environment have been seen as distinct. This view contrasts with the ecological or biocultural approach (Maffi, 2001), which replaces the dualistic view of the relationship between language and the environment with a more complex holistic notion that nature and culture, language and environment are inextricably linked and that the diversity of linguistic and cultural perspectives is a key factor in biological diversity and environmental health. It has been proposed (Harré *et al.*, 1999; Maffi, 2001) that the fit between traditional languages and their natural environment was brought about by the necessity of languages to match the diverse environments in which they are spoken. This leads to the conclusion that the loss of linguistic diversity is a key factor in the loss of biological diversity.

Just as natural ecologies are seen as structures and are defined by functional interconnections between their inhabitants and their habitats, linguistic diversity is seen as similarly structured, with small languages being important for the viability of larger ones and vice versa. Haugen's metaphor of a competitive marketplace has been replaced by a metaphor of protective layers (Mühlhäusler, 1998). In a layered language ecology, the smallest local vernaculars are sheltered from neighboring vernaculars by intercommunity Pidgins, regional Pidgins, and larger lingua francas. The layer metaphor seeks to explain why small vernaculars have become very vulnerable when intercommunity languages are replaced by a single, large, national language.

Applications and Prospects

Any linguistics that increases the number of parameters it considers provides for a larger number of applications and explanations. The language and environment approach has begun to be applied to

language planning, and Liddicoat and Bryant (2000: 305) suggest that "where planning does not consider ecology the result is typically environmental damage, in language as much as in other areas."

Increasingly, language planners consider the social and natural environments of their activities, and in particular the question of whether the introduction of new practices (e.g., literacy or Information Technology), into the environment of indigenous traditional languages might have an adverse effect on their viability. The suggestion that misleading labeling can lead to environmental degradation has been applied to environmental education and signage and has led, for instance, to the renaming of small Australian land animals (previously referred to as rats) with names that remove the perceived undesirability that 'rat' suggests. Examples include Djoorri for the common rock-rat, Palyoora for the plains rat, Tooaranna for the broad-toothed rat, and Rakali for the water-rat (Braithwaite *et al.*, 1995).

Critical environmental linguists have proposed a number of changes in product labeling (e.g., more careful use of the descriptor 'natural' in the United Kingdom) and in the wording of environmental impact assessments. Interestingly, in Wales there is now a requirement of a linguistic impact statement. Critical reassessment of the term 'natural' is also encountered in the debate about causes of so-called natural disasters such as landslides, floods, or droughts, which often turn out to have been triggered by human activity. The idea of languages having an environment or being part of the ecology has produced significant development in the areas of literacy education (e.g., Barton, 1992) and L2 education. Language learning is now seen to take place in a classroom environment or wider social environments that affect its success.

As yet, most writings on language and education have been of a theoretical or critical nature rather than empirical, and the findings that have been made in recent years have been slow in reaching wider public awareness and policy making. Organizations such as Terralingua (<http://www.terralingua.org>), or events such as the 2004 World Expo of Language and Cultures in Barcelona, may help to popularize the ideas addressed here. The establishment of a new publication focused on an ecological approach to language planning (*Current Issues in Language Planning*) should promote new departures in language planning practices.

Evolution of Pragmatics

T Wharton, University College London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Imagine you are walking through a forest. You approach a clearing in the middle of which you notice three tall sticks standing in the ground. Are they young

saplings? No, as you get closer you notice that each stick has been stripped of its bark, that one end of each has been sharpened, and that all three have been forcibly embedded into the ground. This is no natural occurrence; someone has put the sticks there deliberately. You begin to wonder. The sticks are arranged in a straight line each about a meter apart, but the two outer ones are angled inwards, so it's unlikely they're intended as a fence. They are not hidden, so it

is unlikely that someone has left them there to collect later. Since they have been put there deliberately, however, they must have been put there for a reason: why?

This is the kind of question we humans ask a lot. We strive to interpret the actions or behavior of others in terms of the reasons or intentions that might have led them to act or behave in the way they did. In the above scenario, our natural disposition is to try and work out (infer) the intentions behind the action of placing the sticks where they were. Despite the absence of the person who placed the sticks in the ground, you can't help wondering what he or she might have meant by putting them there.

Pragmatists have noticed that this disposition also comes into play when the behavior in question is linguistic. After all, there is much more to understanding the full message that a speaker is trying to convey than simply knowing the meaning of the words themselves. Consider example (1) below:

- (1) Jack: Are you going to Bill's party?
Lily: Bill doesn't like linguists.

The words Lily utters in response to Jack's question have stable, context-independent meaning: linguistic meaning. Jack knows the linguistic meaning of Lily's utterance because he can speak English. The study of this level of meaning is linguistic semantics. But what about the full message Lily intends to convey with her reply – her 'speaker meaning'? This message need not be closely tied to the words she utters at all; it is context-dependent as opposed to context-independent. If I tell you that Lily is a linguist, and that Jack knows this, then the message she intends to convey might be that she will not be going to Bill's party. This level of meaning – what speakers, as opposed to words mean – is the domain of pragmatics.

Of course, pragmatics is many things to many people: there are close to 400 entries in this concise encyclopedia and a quick flick through them reveals modern pragmatics to be made up of a wide range of subdisciplines. There's conversational analysis, the pragmatics of gesture and gender, literary pragmatics and historical pragmatics to name only a few. Indeed, one way of looking at the evolution of pragmatics would be to interpret it as concerning the development of the discipline of pragmatics and to trace its historical development from the writings of Charles Morris and, in the case of English pragmatics, the literature in ordinary language philosophy at Oxford in the 1940s and 1950s (Austin, 1962; Grice, 1989).

The sense of the word 'evolution' used in the title of this essay, however, is the biological one. So for talk of the evolution of pragmatics to make any sense at all, we need to adopt a view of pragmatics that

somehow ties it in with biology, and more generally with the 'natural' world. One way to do so is to adopt a cognitive viewpoint and regard pragmatics as – ultimately at least – a branch of cognitive science or psychology. Such a view owes a lot to the work of Noam Chomsky (2000), who advocates a similar, 'naturalistic' view of language. Construed in this way, pragmatics is not just an academic enterprise, it is:

a capacity of mind ... a system for interpreting a particular phenomenon in the world, namely human ostensive communicative behavior. (Carston, 2002: 4)

This essay, then, concerns itself with how the capacity of mind that is pragmatics evolved. It is not an essay about the evolution of language. The human pragmatic capacity is implicated in the interpretation of all kinds of human communicative behavior: true, that behavior may well – and perhaps most often does – consist in uttering a string of words (accompanied perhaps by a nonverbal behavior such as a gesture or a facial expression), but it could just as easily consist in planting some sticks deliberately into the ground.

The section 'The Pragmatic Capacity' looks briefly at how human communication works, and articulates what the human pragmatic capacity is. This section involves an exploration of what identifies human behavior as 'ostensive' and 'communicative' (the kind of behavior the capacity has evolved to interpret). It also looks at the foundational cognitive machinery the capacity appears to be built upon. The section 'Metarepresentation and Evolution' examines some of the broader questions an evolutionary account needs to address. To what extent is the evolution of this foundational machinery bound up with the evolution of communication? What circumstances might have led to the evolution of such mechanisms, and how did they become a specialized pragmatic capacity? Bearing the answers to these questions in mind, the section 'The Evolution of Pragmatics' presents one version – in the form of a step-by-step account – of the evolution of pragmatics. This progression is based on a 'myth' originally offered in Grice (1982) but in what follows is independently endorsed by research into the evolution of human cognition.

The Pragmatic Capacity

Ostensive Behavior

Whichever of the subdisciplines of pragmatics you choose to focus on, there is a good chance it will owe at least something to the work of H. Paul Grice. Grice (1989) was a philosopher who wrote

some highly influential papers and delivered the William James Lectures – called ‘Logic and Conversation’ – in 1967, out of which modern pragmatics developed.

Part of Grice’s legacy is that our view of how humans communicate has changed completely. According to the traditional ‘code model’ of communication – which dates back to Aristotle – a communicator’s thoughts are translated into a signal by the use of a code (in this case, language), and translated back from the signal by an audience into the original message. Post Grice, human communication has come to be regarded as an intelligent, intention-driven, inferential activity. Rather than simply being a process of coding and decoding, human communication is achieved by a speaker giving evidence of an intention to inform the hearer of something, and the hearer inferring a conclusion from this evidence.

Consider the following example. If a colleague catches your eye at a meeting and looks in a deliberate manner towards the door (perhaps accompanied by a mimed yawn), then you might infer that your colleague is bored and wants to leave. But this communication is not achieved by coding and decoding. Rather, what the behavior made clear was the fact that your colleague had an intention to inform you of something: communication was achieved by your inferring what this was, rather than decoding your colleague’s actions.

Of course, to adopt this view of communication is not to deny the role of coding and decoding in the special case of linguistic communication. In order for Jack to derive Lily’s intended meaning in (1), he does indeed need to know the linguistic meaning of the sentence that Lily utters. Crucially, however, he only needs to know it because it provides him with a clue to the speaker meaning that she intends to convey. Her utterance makes clear that she intends to communicate something to him, and he has to infer what the content of this intention is.

There have been various proposals as to how this inference is made. A common story (initially proposed by Grice) has it that Jack begins from the presumption that Lily is being cooperative in her response (perhaps by following a ‘cooperative principle’ and ‘maxims’), or ‘relevant’ in some sense of the word (see **Relevance Theory** – Sperber and Wilson, 1986/1995). Jack uses this presumption to construct the best available hypotheses about Lily’s intended meaning. Since Jack has asked her a question, he obviously expects an answer, and Lily would be being neither cooperative nor relevant if her only intention was to communicate to Jack that Bill doesn’t like linguists. Jack knows, however, that Lily is a linguist, and based on the presumption

that Lily is cooperating (or that she believes it is relevant to tell him that Bill doesn’t like linguists), Jack can infer that Lily’s intention is to communicate that she will not be going to Bill’s party. Whatever story you decide to tell, as well as possessing the requisite semantic competence, in order to interpret speaker meaning, hearers must possess something more, and use this information to work out what was meant.

This ‘something more’ involves a range of factors. Since it involves inferring the intentions of others, it presupposes an awareness that other people have intentions in the first place. This observation is not a trivial one: other people’s intentions and mental states generally are not objects to be perceived in the world in the same way as are their faces or bodies; they are ‘out there,’ but they are invisible. Equally, it presupposes the existence of mechanisms by which these hypotheses about the intentions of others can be represented: a ‘framework,’ if you like, on which representations of the thoughts and intentions of others can be hung. Finally, it presupposes the existence of standards or expectations about proper communicative behavior according to which hearers form the best hypothesis about a speaker’s intended meaning.

On the last of these points, I will have little to say; not because the existence of such standards or expectations is not linked to the evolution of pragmatics, but because the attempt here is to tell a much more general story. Suffice to say, humans are rational beings, and successful communication (in general) proceeds along rational lines according to such standards or expectations. In what follows, I will be interested in the extent to which human communication involves the expression and attribution of intentions (and what kinds of intentions are expressed and attributed), and the mechanisms that underlie our ability to do this.

So, what kinds of intentions are involved? A first suggestion might be that all that is required for an act to be ‘ostensive’ or ‘communicative’ is that the agent of the act has an intention to impart some information to an audience. A moment’s reflection, however, reveals that having this intention is not enough. If I intend to inform you that I want a particular book for my birthday, I might decide to leave a magazine casually open at the page where I have ringed a review of the book in question with a pen. Notice that in this scenario, I don’t want you to know that leaving the magazine for you is my intention: I leave the magazine looking as if it has fallen open at this page naturally.

Many people (including Grice) see a sense in which this kind of example is problematic; those who do see the problem as residing in the fact that there is

something covert about the way I have behaved. Indeed, there is a sense in which the kind of transfer of information in this example doesn't even count as 'communication,' which – after all – we feel to be a joint activity. In any case, even if we do regard this situation as an instance of communication, it is certainly not the kind of communication that is reliant in any way on the expression and attribution of intentions. It can't be, since you are unaware I have an intention to inform you of anything. In this example, my behavior is not 'ostensive.'

For an act or behavior to count as ostensive, we need another intention. This one is the 'higher-order' intention that the intention to impart some information be revealed. So in the above example, I would not only need to intend to inform you that I would like the book for my birthday, but also intend you to **realize** that this is my intention. I could achieve this higher-order intention in a variety of different ways. One way would be to make it obvious to you that I have left the magazine open deliberately: I might leave it out in a highly prominent position – perhaps open on your desk; another would be to write 'Birthday present please!' next to the circle I have drawn around the review; still another would be to point out to you the fact that I have circled the review as you enter the room. In keeping with the terminology adopted by Carston in the above quote, I call behavior with this kind of higher-level intention 'ostensive communicative behavior.'

Returning to the example in my opening paragraph, one reason that the three sticks deliberately stuck in the ground attract your attention so is that they may be evidence to you that someone has the higher-order intention that you realize that they have a basic intention to impart some information to you. Having recognized the higher-level intention, you are naturally predisposed to try and infer what this basic intention is.

Theory of Mind

The capacity to infer this kind of complex intention is closely related to – perhaps even a part of – the human ability to attribute mental states in general, including beliefs, intentions, and desires: the ability widely known as 'mind-reading' or 'theory of mind' (Baron-Cohen, 1995). Imagine two people running past you quickly down a road, one behind the other: A, the person behind, is gesticulating angrily; B, the person in front, is looking over his shoulder with a certain expression of fear. Rather than viewing their motion as you might view the random motion of two billiard balls – one apparently 'following' the other around a billiard table – it is an automatic

response to interpret their behavior in terms of the mental states that underlie it. At a basic level, you would perceive their actions in terms of their goals and desires; in terms of the person behind – A – wanting to catch the second – B, or B's desire to escape.

However, as well as these basic concepts, you would also attribute to A and B more complex mental states (Leslie, 1994). So, for example, it might be clear to you that A **believes** that B has done something wrong (the complex mental state underlying A's goal), and that B believes that A **intends** to catch him (the complex mental state underlying B's desire to get away). Notice that the kind of beliefs you attribute may well be incompatible with the beliefs you yourself hold: you have no problem attributing to A the belief that B has stolen his wallet, even though you know that B has not (because, for example, you have A's wallet in your pocket).

Since the ability underlying theory of mind is recursive, our own and others' mental states can be represented in a multilayered way, to a number of different levels. Watching the chase, you have no problem entertaining the thought that B believes that A believes that he has done something wrong, or even that A believes that B believes that A believes that he has done something wrong (or even, for that matter, that B believes that A believes that B believes that A believes that he has done something wrong, etc.). The mind-reading ability – and, therefore, the pragmatic capacity – is underpinned by a more general ability that humans have to represent other representations, or, to use another current piece of terminology, to 'metarepresent.' The pragmatic capacity is built upon this ability.

The kind of representations humans might metarepresent can be either public ones – such as the linguistic utterance in example (2), or mental – such as the thought in example (3). The pragmatic capacity must at the very least involve the ability to entertain and manipulate metarepresentations as complex as the one(s) in (3) (where the metarepresentation is the emboldened part):

- (2) Lily said **that Bill doesn't like linguists.**
- (3) Lily intends **me to realize that she intends to inform me that she isn't going to Bill's party.**

Developmental psychologists have designed experiments to discover at what age this ability emerges in humans (by about four years old), and have shown that it is subject to pathological breakdown. Autistic individuals, for example, typically fail tests in which they have to explicitly attribute to others beliefs incompatible with their own, and this inability is

generally taken to be evidence that they lack full-blown theory of mind (Leslie and Happé, 1989; Happé, 1994). While some autistic individuals acquire language, the condition is typified by an inability to communicate anywhere near 'normally': those who **do** understand words find it hugely problematic, sometimes impossible, to understand what speakers mean by them.

Metarepresentation and Evolution

Over recent years, there has been a tremendous amount of research into the human mind and the evolution of human cognition. In particular, people have questioned the long-held view that humans are endowed with general, all-purpose cognitive abilities, which they bring to bear on any cognitive task set before them. Philosophers of mind (Fodor, 1983) have argued that the mind (or part of it) is modular: that it is an organized system of individual, highly specialized mechanisms. The existence of conditions such as autism lends support to this proposal. Cognitive scientists and evolutionary psychologists argue that these domain-specific mechanisms have evolved as adaptations to deal with specific challenges in the ancestral hominid environment (Hirschfeld and Gelman, 1994). The mind, viewed in this way, is an 'adaptive toolbox.'

We are now in a position to begin asking evolutionary questions, such as those I posed in the introduction. Indeed, since the pragmatic capacity is some kind of specialized metarepresentational ability, we can be more specific in the kind of questions we ask. Before we look at possible scenarios in the evolution of the pragmatic capacity, we need to look at the evolution of the metarepresentational ability.

All nonhuman animals with cognitive capacities possess the ability to represent, but the ability to entertain representations of representations – and representations of representations of representations, etc., – appears to be as unique to humans as the ability to use echolocation is unique to bats (Sperber, 2000b: 117). Indeed it has even been suggested that the sophistication of the human metarepresentational ability underlies our ability to be aware of our own thoughts, and is therefore implicated in one of the biggest mysteries of all: human consciousness.

A striking feature of much of this work is that while there is disagreement on the factors that may have led to the evolution of such an ability, there is broad agreement at least that it could have evolved – or at least begun to evolve – independently of communication. One view (Cosmides and Tooby, 2000) proposes that the ability to 'detach' ourselves – mentally, at least – from the here-and-now, and

entertain a representation of a situation as something other than a true belief about the world, would have improved our adeptness in reacting and responding to local aspects of the environment. This ability would have enabled humans to adapt to the environment spontaneously – for example, by making plans – rather than having to adapt (as does the rest of the animal kingdom) on an evolutionary time-scale. Such improvisational skills would have proved highly adaptive.

Another view – The Machiavellian Intelligence Hypothesis (Byrne and Whiten, 1988) – suggests that as well as the task of interacting with the natural environment, a particular challenge for humans (and, indeed, primates generally) was the task of dealing with the complexity of social interaction. In the human case, it is proposed that this challenge led to a kind of 'Cognitive Arms Race,' within which human cognitive abilities spiraled – mainly in order to help individuals compete with their conspecifics and perhaps outmaneuver them. The ability to interpret behavior in terms of the motives behind it would have given an individual strong predictive powers, and it would have been adaptive to become more and more adept at working out the thoughts and feelings of others (Humphrey, 1984).

A recent paper (Tomasello *et al.*, in press), points out that as well as evolving the ability to compete and deceive, humans also evolved the ability to collaborate and cooperate. This unique human disposition to share intentions – in which a metarepresentational ability is also implicated – may form the foundations upon which much human interaction (and possibly human culture) is built.

Of course, sensing how someone else is feeling does not necessarily require complex metarepresentational abilities. Well before full-blown human theory of mind develops, a young infant can sense the emotional state of its carer. Indeed, a great deal of the way humans sense the emotional states of others is done in other – nonintentional – ways. Consider the automatic way in which we interpret facial expressions, or the way panic spreads through a crowd. The cries that alert others to danger in this situation may not be uttered with intentions, and are on the whole not understood by attributing intentions. Presumably at some early stage in our evolution, this was how we were able to sense whether or not people were friendly or a threat, or whether a situation was safe or dangerous.

Before the evolution of metarepresentation, our ancestors were 'ignorant of an inner explanation for their own behavior' (Humphrey, 1984: 49). But once they were selected, rudimentary metarepresentational abilities could have spiraled and spiraled

until they eventually led to the evolution of the kind of complex mechanisms that underlie full-blown theory of mind. Tooby and Cosmides (1995: xvii) put it like this:

Unobservable entities ... are 'visible' to natural selection ... Over innumerable generations, the evolutionary process selected for modules ... that could successfully isolate, out of the welter of observable phenomena, exactly those outward and visible signs in behavior that reliably signaled inward and invisible mental states.

At a crucial evolutionary stage, then, humans somehow became aware that they were living not just in a world populated by other faces and instinctive cries, but a world populated by other minds.

There is little evidence so far that nonhuman animals possess mind-reading abilities to anything like the degree of sophistication found in humans (Premack and Premack, 1983; Hauser, 1996) and hence recognize that their signals **mean** anything. In many ways, this lack of evidence could be seen as presenting problems for an evolutionary account of, for example, theory of mind (Plotkin, 1997). Our common ancestor with the chimpanzee (who lived about 7 million years ago) may have possessed imitative capacities, and these may have been refined into metarepresentational abilities along the hominid line since then, but there is scant evidence among modern-day chimpanzees that they possess anything other than the most rudimentary metarepresentational abilities. The communicative skills of chimps are very basic; indeed, even the more sophisticated nonhuman animal communication systems work along entirely different lines to human communication.

Consider vervet monkeys: when a vervet sees a predator, it emits a specific alarm call that alerts other monkeys in the group: a loud barking call for leopards; a short, double-syllable cough for eagles; and a 'chutter' sound for snakes (Cheney and Seyfarth, 1981). However, on hearing a vervet monkey produce an alarm call, a vervet need not presume that the calling vervet is being cooperative or relevant in order to work out precisely what it means. Vervet monkeys don't mislead, and they don't answer questions indirectly. Communication is achieved without either the sending or receiving animal consciously recognizing that the signal means anything. Indeed, studies suggest that the vervet has very little control over the production of the call itself; it is more as if vervets exploit a reliable correlation between hearing an alarm call and there being a predator in the vicinity rather than that there is any 'meeting-of-minds.' What we need to show is why, and how, human communication evolved along such radically different lines.

The Evolution of Pragmatics

To recap: the human pragmatic capacity is "a system for interpreting ... human ostensive communicative behavior." Ostensive behavior is behavior that reveals a certain complex type of intention, and so the pragmatic capacity is a system that makes the recognition and attribution of such intentions possible. In other words, it is a specialized version of the human ability to attribute mental states.

To what extent would it need to be a specialized version of this ability? There are a number of issues to bear in mind. First, the types of 'meaning' that a speaker can convey by producing an utterance are generally much more complex than the types of intention normally attributed to someone in order to explain their observed behavior. Second (and related to the first), we often attribute intentions to others by observing the effects of their actions, deciding which of those effects they might have desired, and attributing to them the intention to achieve those desired effects: the 'chase' between A and B is a good example. However, a speaker will achieve very few effects by producing an utterance unless she is first understood, so the normal procedures for recognizing the intentions behind ordinary noncommunicative actions won't work: the hearer can't first observe the effect of an utterance and then infer what it meant.

Thirdly, in order to understand intentional communication – as opposed to ordinary noncommunicative behavior – it is necessary to be able to attribute several layers of metarepresentations; yet young children below the age of four – the same children who (as do autistic subjects) fail standard theory of mind tests – master verbal communication quickly and effortlessly well before this age. Based on these and other arguments, Sperber and Wilson (2002) propose that the theory of mind inferences central to the interpretive process are performed by a domain-specific 'comprehension' mechanism or module. This comprehension module is an evolved submodule of the theory of mind module: another part of the human 'adaptive toolbox.'

Consider the following scenarios, which are intended to be seen as taking place over many, many generations. Imagine a tribe of our hominid ancestors. When these ancestors are tired, they involuntarily yawn. To other hominids, a yawn reliably correlates with tiredness in the same way that, say, black clouds correlate with rain (or – though there are differences – the vervet alarm call correlates with the presence of a predator). Crucially, though, a metarepresentational ability is already evolving along the hominid line: perhaps to help better exploit the

environment; perhaps to facilitate more complex social interaction. Our ancestors already have rudimentary metarepresentational abilities, and the evolution of the pragmatic capacity should be seen against the backdrop of this independently-evolving metarepresentational prowess.

In the first scenario, one member of the tribe – call him Jack – is able to fake a yawn. Another member – call her Lily – recognizes the voluntary, spontaneous nature of Jack's yawn. At this stage, the fact that Lily recognizes that Jack has faked the behavior may lead her to come to the conclusion that he is not tired. Jack is producing a normally involuntary behavior voluntarily and could, after all, be trying to deceive her.

Now, let's move to scenario two. In this scenario, we imagine that not only does Lily recognize that Jack has faked a yawn, but also that Jack intends Lily to recognize his behavior as such. Jack and Lily can already metarepresent in a rudimentary way: the metarepresentational ability, recall, is evolving independently. He is 'aware' of his intention, and is metarepresenting its content – as in (4) – and she is entertaining the metarepresentation in (5) below:

(4) I intend that Lily recognizes my intention to fake this yawn.

(5) Jack intends that I recognize that he intends to fake a yawn.

The possibility of deception – a plausible interpretation in the previous stage – is no longer the only possibility. Of course, Lily is still likely to be in something of a quandary. Jack is not only apparently faking a yawn, but also doing so overtly. It does not seem unreasonable to suggest that one way Lily might proceed is to presume that Jack is pretending or being playful. By the time such a conclusion is arrived at by Lily, we have reached a third scenario.

Consider now a fourth scenario. Lily has come to suppose not that Jack is playing a game, but rather that Jack is trying to get Lily to believe (or at least accept) that he is, in fact, tired. That is, that Jack's intention in producing the normally involuntary behavior voluntarily is to communicate the very same thing the involuntary behavior normally conveys. By this stage, of course, Lily may wonder precisely why Jack should choose to use a faked yawn to communicate tiredness as opposed to an involuntary one. There may be various reasons; one reason may be that Jack's voluntary production might only be intended to indicate some, as opposed to all, of the features associated with an involuntary yawn. Perhaps Jack is tired, but not so tired as to yawn involuntarily; perhaps he is feeling drowsy because he feels

unwell. Recall the example described in the section 'The Pragmatic Capacity,' where a faked yawn is used to communicate boredom. Whatever he intends to inform Lily, he is – at this stage – entertaining the metarepresentation in (6):

(6) I intend Lily to realize that I intend to inform her that ...

And Lily, if she recognizes his intention, is entertaining the metarepresentation in (7):

(7) Jack intends that I realize that he intends to inform me that ...

By the time we have reached this scenario, Jack's behavior is 'ostensive' in the sense defined earlier, and Lily has engaged in the kind of pragmatic inference modern-day humans employ. If such a system of communication can be shown to have been advantageous, we can imagine that the cognitive abilities necessary to engage in such communication would have been selected for.

What might the advantages be? Why should already-evolving metarepresentational abilities be recruited – or 'exapted' (Gould, 1980) – for use in communication? The main advantage is that it is the intention behind the behavior, rather than the behavior itself, which plays the main role in Lily's successful understanding of Jack. Communicators have reached a stage where the ostensive behavior need have nothing more than a very tenuous connection with the message a communicator intends to convey, so long as the communicator thinks the audience can infer it. In short, hominids have gone from only being able to communicate by exploiting 'natural' correlations and being able to communicate only a limited number of things, to also being able to communicate non-naturally, employing systems of representations, and being able to communicate virtually anything at all.

Of course, communication along these lines would at first have been slow and effort-consuming. The limitless possibilities such a system would have opened up, though, would have given humans an enormous advantage that presumably came to outweigh the costs. If we imagine scenarios such as these taking place generation after generation, and consider them against the back-drop of the developing metarepresentational ability, we have a plausible account of how ostensive communicative behavior and – moreover – the specialized cognitive mechanisms required to interpret such behavior could have evolved. Over evolutionary time, slow, conscious reasoning processes would have come to be replaced by 'fast and frugal heuristics' (Gigerenzer and Todd, 1999) which made this kind of pragmatic inference automatic. In

modern humans, they are carried out by a dedicated submodule of theory of mind: the pragmatic capacity.

Now Jack is walking through a forest. As he approaches a clearing, he hears an animal cry. In the middle of the clearing, he sees a large rodent disappearing slowly into a wide pool of quicksand. He becomes tense. His tribe uses this route frequently, and even if he shouts at the top of his voice, he knows they will not be able to hear him from here. He thinks. He has to go on, but he must warn his people. If he places a log in front of the quicksand, there is a chance that some people will walk around the log and hence successfully avoid the quicksand. Many, however, will simply presume that the log has fallen naturally and step straight over it into danger. He thinks again. He walks over to a small tree and cuts off three long, thin branches. He strips off the bark and starts to sharpen them.

F

Face

F Bargiela-Chiappini, Nottingham Trent University, Nottingham, UK

Background

A search for 'face' in the on-line *Oxford English dictionary* (OED) yields pages on this polysemic entry. It also illuminates the cultural and psychological dimensions of the construct that lies at the heart of a well-known model of linguistic politeness expounded by Brown and Levinson in their seminal work *Politeness: some universals in language usage* (1978, 1987) (see **Politeness**). The Western character of their (positive and negative) face derives from an Anglo-Saxon understanding of the rational individual who seeks to protect himself or herself, and others, from Face-Threatening Acts (FTAs). In spite of its claim to universality, the politeness model that stems from this characterization of face is also, inevitably, culture-biased (see **Intercultural Pragmatics and Communication**).

In reaction to this, a critical reappraisal of Brown and Levinson's notion of face has engaged scholars beyond the Anglophone world, who have brought to their analyses insights from psychology, philosophy, and anthropology. In particular, critique from Asian linguists has now grown into a consistent contrastive body of research, which has expanded to include perspectives from Southern Europe (e.g., Turkey, Greece, Spain, Italy), South America (e.g., Ecuador, Argentina), and South Africa, thus widening considerably the cultural spread of the debate.

If it is thanks to two British anthropologists (Brown and Levinson) that linguistic politeness rose to become the subject of ongoing scholarly debate, it is too easily forgotten that it was an American sociologist who gave us the powerful account of 'face' that stands at the heart of it. Not a universal account, however; in fact, Erving Goffman's 'face' is American in many of its facets, and yet an original contribution to the modern study of the social and psychological relevance of this arguably universal construct to politeness research and human interaction (see **Goffman, Erving**).

Face as a philosophical construct boasts a history that dates to ancient civilizations. For example, the Náhuatl people who inhabited Central America would use the expression 'face-heart' (Spanish *rostro-corazón*) to define personhood. In their understanding, "face seems to refer to the physiognomy of the self while the heart is the dynamic aspect of self" (Jiménez Cataño, 1993: 72) (my translation). In modern times, among the more defining influences on Goffman's early work and his conceptualization of face are Chinese and American Indian sources and the work of the French sociologist Émile Durkheim.

'Face' According to Goffman

Even though Goffman was primarily concerned with uncovering the rules governing social interaction, his treatment of 'face' leads the reader to believe that he saw it as the hub of interpersonal dynamics; in fact, for Goffman 'face-saving' was shorthand for 'the traffic rules of social interactions' (1967:12). His concept of face, unlike Brown and Levinson's later understanding of it, seeks to accommodate both strategic and social indexing behaviors and is best apprehended in the context of social order as ritual. Equilibrium is maintained by interactants making choices informed by moral rules. In turn, the social morality underpinning Goffman's order consists of values such as pride, honor, dignity, consideration, tact and poise, perceptiveness and feelings, all of which the self expresses through face. Within the wider social order, face maintenance is a condition rather than the objective of interaction.

Émile Durkheim, the French thinker, saw social action as symbolic ritual enacted through positive and negative rites, hence Goffman's definition of the person as a "ritual object," a "deity," and "his own priest" (1967: 55). However, Durkheim also envisaged solidarity as the glue of the social order. Solidarity between actors would aim for the fulfillment of obligations toward others as a condition for the maintenance of equilibrium. Goffman's interactant is certainly more individualistic, but avoids the egocentrism of Brown and Levinson's

idealized agent. Ultimately, for Goffman as for Durkheim, organizational order comes before the safeguard of the individual self, which can be asked to sacrifice his or her face (with the ensuing embarrassment) for the gain of society (1967: 112).

In 1944, the *American Anthropologist* published Hsien Chin Hu's seminal account of the Chinese concept of 'face.' A decade later, Goffman acknowledged his debt to Hu in his discussion of a Western version of 'face.' Goffman's social psychological definition of face is that of 'the positive social value a person effectively claims for himself by the line others assume he has taken during a particular contact' where a "line" is the interactants' self and others' evaluation (1967: 23). Self-respect and consideration are safeguards for one's own and others' face in social encounters. These social values underline the interdependent character of Goffman's actor whose face he considers sacred (1967: 19). Face maintenance requires a ritual order, that is 'acts through whose symbolic component the actor shows how worthy he is of respect or how worthy he feels others are of it' (Goffman, 1967: 19). For Goffman, the contemporary and still enduring Anglo-Saxon values of independence and privacy have swung the balance from a Durkheimian collective self to a self-aware, more individualistic self.

Goffman's 'face-work' consists of defensive (saving one's own face) and protective (saving others' face) practices exercised simultaneously, another indication of the social value that he attached to face. "Avoidance" rituals, "corrective" processes, and the "aggressive use of face-work" are also discussed by Goffman in some detail alongside the tacit cooperation that makes face-work possible. Brown and Levinson's model seems to have given preeminence to the first three practices, thus emphasizing the self-defensive, negative posture of their ideal agent.

For Goffman, "tact," "reciprocal self-denial," and "negative bargaining" (favoring one's counterpart) signal the degree of social awareness and concern for others, possibly motivated by self-preservation, which interactants would display as a "ritually delicate object" (1967: 31). In spite of later developments in politeness research that somewhat obscured the originality of Goffman's face, his notion remains a primary object of interest for scholars engaged in the situated study of interpersonal behavior in general and of 'polite behavior' in particular.

Brown and Levinson's 'Face' and Its Critics

Brown and Levinson's positive and negative face is a cognitive, abstract, culture-dependent construct

attributable to a rational agent; it makes extensive use of Durkheim's negative (avoidance) rituals. The dualistic notion of face and the emphasis on negative face and the notion of 'imposition' have attracted extensive criticism in subsequent Chinese and Japanese studies of politeness, as well as among other non Anglo-American scholars. Although Brown and Levinson acknowledge Durkheim as their source for negative and positive rites, their understanding of the sociologist's original concepts is substantively altered in their model; their ideal rational actor is busy protecting own and others' face, rather than giving, enhancing, or maintaining face. Emotions, when accounted for, are also means of face-protection.

Such a reductionist perspective has progressively laid bare the need for a sociopsychological and affective construct of face that resonates again with Goffman's original motivation for the study of interaction as being "not about the individual and his psychology, but rather the syntactical relations among the acts of *different persons mutually present to one another*" (1967: 2) (*italics added*).

It is Brown and Levinson's negative face (and negative politeness) that have been singled out for intensive scrutiny on grounds of cultural relativity. Further, their outline of positive and negative face as mutually exclusive in interaction has been challenged by empirical research that indicates, instead, the coexistence of many face wants calling on simultaneous positive and negative face-work. Similarly, the assumptions that only one type of face can be threatened at any given time and that Face Threatening Acts (FTAs) can be analyzed out of context are highly problematic.

The crosscultural validity of Brown and Levinson's model has buckled under the criticism of suffering from British 'cultural bias' (Baxter, 1984). Research in linguistic politeness in the 1990s indicated a split between cultures where face is a key explanatory construct in interpersonal behavior and those where other values such as discernment, deference, and respect play a more important role. Face and face-work will operate differently in socially stratified cultures (e.g. Japan and Mexico, where normative politeness is dominant) compared to status-based cultures (such as China and Korea), where normative and strategic (volitional) politeness coexist. Where status is allegedly less marked in interpersonal interaction and normative politeness is less in evidence (e.g., Northern Europe and North America), the concern for face remains nevertheless relevant, even if expressed in a more understated way.

The consolidation of psychology research on the social self and social identity has opened up new contexts of relevance for the dynamics of face and face-work, calling on a modified model of face

and politeness that breaks free from the straitjacket of cognitivist psychology. Another exciting development is the emergence of indigenous psychologies from Asia and Africa which, instead of testing Western formulations, may develop their own analytical models and constructs to make true crosscultural comparison possible.

Future of Face Research

For all the criticism of ethnocentrism that their model has generated, Brown and Levinson's work can boast an unmatched and continuing level of interest within the field of linguistic politeness research. Twenty years on, new insights from social and cultural psychology point in the direction of a culture-situated, dynamic understanding of face that gives consideration to other factors such as personal values, one's own self-concept, self-identity in various groupings, role expectations, and normative constraints (Earley, 1997: 95–97). After years of established disciplinary research in politeness, especially in anthropology and linguistics, face is becoming a privileged topic for interdisciplinary research. In addition, its cultural sensitivity calls for more international collaborative research if its sociocultural and philosophical roots are to be uncovered for further comparative analysis.

On a more abstract level, one could imagine face as a bridging concept between interpersonal interaction and social order in the sense that face, at the micro-level of verbal and nonverbal behavior, encapsulates and dynamically displays the manifestations of (macro-level) cultural values. Situated discourse would thus become the epistemological

locus where observation and interpretation of face and face-work take place as within their most expressive environment. Alongside psychologists, anthropologists, and sociologists, in future social theorists may be called upon to explore a powerful construct that thus far has occupied but not yet exhausted the endeavors of most politeness scholars.

Family Speak

M Laforest, Université du Québec à Trois-Rivières, Trois-Rivières, Québec, Canada

© 2006 Elsevier Ltd. All rights reserved.

To work on family speak is to be interested in language as it is used in the private space. Family interactions have special features that make them a particularly revealing object of research. As in any interaction, power relationships exist, especially between parents and children (*see Power and Pragmatics*) But the intimacy that prevails in a family setting is unique: no other context presents so great a degree of proximity between participants or so great a volume of shared references owing to a common past

(*see Shared Knowledge*). The intimacy of the family context affects discourse in three ways: (1) informality, since family speak is the most informal discourse there is, (2) the major role played by implicit understanding due to shared references, and (3) the particularly high number of metapragmatic or meta-discursive comments (especially in exchanges with children), since the home is a privileged venue for pragmatic learning (*see Language Socialization; Metapragmatics*).

Work on family discourse allows us to reconsider some important issues in pragmatics, namely:

1. The socialization of children. The family is the matrix of socialization and of the constitution of

identity. As a result, family interactions offer an ideal means for observing processes involved in the acquisition of pragmatic competencies and the transmission of social and cultural values. Various strategies related to these processes have been studied, notably the use of control acts (particularly well documented), topic management, and metapragmatic comments. Narrative and explanatory talk have also been the object of interesting studies (*see Narrativity and Voice*). Several of the works listed were conducted from a cross-cultural perspective and highlight the differences observed from one linguistic community to another (*see Scaffolding in Classroom Discourse; Pragmatics: Overview*).

2. Politeness. In canonical models of politeness (notably Brown and Levinson, 1987), face-threatening acts (FTAs) are classified based on how directly or indirectly they are carried out, and the greatest politeness is associated with the greatest degree of indirection. It appears, however, that nagging, insults, complaints, and other FTAs occur frequently in family conversations, often in a direct form, without causing a deterioration in the family climate. These acts are not perceived as crude. In family speak, therefore, the direct nature of the act does not indicate impoliteness, and facework is done differently. By documenting how FTAs

occur in the context of intimacy, works on family speak therefore help relativize the scope of norms that some consider universal in terms of politeness (*see Politeness; Face*).

Fillmore, Charles J.

D Stein, Heinrich-Heine-Universitaet Düsseldorf, Duesseldorf, Germany

© 2006 Elsevier Ltd. All rights reserved.

Charles J. Fillmore received his Ph.D. in Linguistics at the University of Michigan in 1961. After spending ten years at Ohio State and one year at the Center for Advanced Study in the Behavioral Sciences at Stanford, he transferred to the Linguistics Department at Berkeley. He was elected Fellow of the American Association of Arts and Sciences in 1984 and was President of the Linguistic Society of America in 1990.

Fillmore's work centers around interconnected foci of research. The major focus is the interface of syntax and semantics, concentrated on the analysis of English and Japanese with an emphasis on the semantics, in the broadest sense, of individual expressions. Fillmore has successfully applied this type of analysis to several types of discourse, focusing especially upon

the deictic potential of individual expressions; for example, he has made use of literary discourse as a means of explaining the perspective exploited especially by modern literary discourse, such as indirect free style. His analysis of semantics and syntax was later elaborated upon in a systematic way in the form of 'construction grammar,' the integrated description of the semantics and syntax of subsentential units.

Fillmore's work has had a major impact on semantic and syntactic analysis by arguing for a separate level of analysis for 'case roles' such as agent, patient, and locative, in an effort to account for the semantics of sentences and the semantic interdependencies, manifested syntactically, between constituents, much in the vein of valency theory. Although there are regular correspondences with syntactic functions of phrases like subjects and objects, such as that between syntactic subjects and agents, these case roles have to be set up as a logically separate layer of semantic intuition and, consequently, of linguistic description,

since in other cases, and in variant typological scenarios, the only argument for the association of case roles with syntactic function is based upon statistical tendencies of various strengths.

Fillmore's work constitutes a significant contribution not only in terms of linguistic theory, but also to the linguistic description of English and Japanese. The application to a major corpus of English (based on the British National Corpus, amongst other materials) of his descriptive approach is at the center of a major corpus-based lexicographic project ('Frame Net') with the aim of a semantic-syntactic description of the lexical units of English. These lexical units are conceived of as triple layers of information: a semantic case (such as agent), a grammatical function (such as subject), and a phrase type (such as NP). The semantics of a lexical unit, in particular each individual sense of a polysemous unit, is conceived of as based on a semantic frame with a script-like inferential structure associated with types of situations, objects, or events. Any target so characterized is also characterized by dependents that are part of this frame. The core elements of a particular frame uniquely specify the particular sense of a lexical unit. Meaning differences between different senses of polysemous items are reflected in different kinds

of syntactic realizations of the elements of the frame defining the whole lexical unit. The aim is to ultimately provide an on-line-accessible database that contains all the semantic-syntactic information a native speaker possesses of a lexical unit.

Formulaic Language

A Wray, Cardiff University, Cardiff, Wales, UK

© 2006 Elsevier Ltd. All rights reserved.

Introduction

"a vast proportion of verbal behavior ... consists of recurrent patterns, of linguistic routines" (Hymes, 1962/1968: 126).

"our language does not expect us to build everything starting with lumber, nails, and blueprint, but provides us with an incredibly large number of prefabs" (Bolinger, 1976: 1).

Formulaic Language and Novel Language

It is universally recognized by linguists that human language is unique in its expressive potential because it enables us to produce and comprehend utterances that we have never encountered before. Most research into linguistic form has therefore tended to focus on the mechanisms by which that flexibility operates. However, evidence from psycho- and sociolinguistics,

and in recent years also from corpus linguistics, indicates that there is a mismatch between the potential that human language has for novelty and the much smaller set of patterns that are actually found in our everyday linguistic behavior. As Pawley and Syder (1983) point out, there are things that the theoretical models indicate we **can** do, but which don't seem to be done as often as they might be.

Of course, it is no surprise that languages make possible the expression of ideas that no one has ever yet needed to express. The cutting edge of human creativity is the capacity to capture a new idea and convey it to others, and unless language can facilitate that, cultural, technological and philosophical development will be greatly hampered. What is less clear is why messages that **are** often needed should also eschew the full creative potential of language. For although language makes it possible for us to express an idea in many different ways, native speakers of any given language know that there are certain preferred formulations of it. Pawley & Syder (1983) point out, for instance, that in English we say that the time is 'six forty' or 'twenty to (or before) seven,' not 'a third to

(or before) seven' or 'seven minus twenty.' This is a matter of convention, not any grammatical or semantic restriction, and languages vary in their practices. In French, 'six forty' is expressed as *sept heures moins vingt* ('seven o'clock minus twenty'), while in German, *halb sieben* ('half seven') means 'half past six,' that is, half an hour before seven.

A Preliminary Definition of Formulaic Language

As with many complex phenomena, a complete definition of formulaic language is difficult to capture until a great deal is understood about it. A fuller exploration of the definition and identification of formulaic language is provided later. For now, it will suffice to say that, for most researchers, the term 'formulaic language' refers to two or more words which may or may not be adjacent and which have a particular mutual affinity that gives them a joint grammatical, semantic, pragmatic, or textual effect greater than the sum of the parts. For instance, the word string *in order to* conveys a relationship between two actions without it being clear how the three constituent words contribute to expressing that relationship. The word string *get away with you* means 'don't be ridiculous,' which is not a literal interpretation of the words. The word string *happy birthday* is a strongly favored routine for expressing good wishes, even though, by analogy with Christmas greetings, *merry birthday* ought also to be possible.

Even these few examples already highlight a number of issues that must be continually addressed when researching formulaic language. Firstly, it is clear to even a casual observer that most, if not all, formulaic word strings derive from novel constructions. This raises the question of how we are to decide precisely when a configuration should be considered formulaic rather than novel. Is *have a nice day* a formula or not? It certainly seems to have pragmatic connotations over and above its composite parts, yet if someone were to create, as novel, a grammatical sentence to wish someone a pleasant time from now until nightfall, it could well come out in precisely these words. A second, related issue is how much linguistic knowledge we should attribute to users. In the expression *if I were you*, the verb form is a subjunctive. Many people now do not use the subjunctive after *if*, but still use this expression. Are they exceptionally applying knowledge that they do in fact have, or do they have a way of producing the expression without needing to understand why – or indeed perhaps without even noticing that – the verb takes a form they could not generate using their own linguistic system? Thirdly, what is the relationship between units of processing and words on the page? The vagaries of English writing are legion: we write *into* as one word but *out*

of as two, for instance. Is *in order to* really *inorderto*? What would the implications be for viewing *take heed* as *takeheed*, since we can say *due heed was taken* and *took heed* as well? The point is not whether answers can be proffered, for they certainly can, but that any given answer reflects certain assumptions and priorities in linguistic modeling. When the questions are asked, it is these assumptions and priorities that are under examination.

The Focus of Research into Formulaic Language

Researchers of formulaic language are interested in questions such as: Why do conventionalized forms exist and persist? What determines which forms become conventionalized? What prevents or permits the replacement of one conventionalized form by another? How does the deliberate choice of a less conventionalized formulation impact on the way the message is perceived? How do children balance learning to be idiomatic with learning the underlying linguistic system that predicts so many under-used alternatives? Why do post-childhood foreign-language learners find it so difficult to identify the conventionalized nativelike form from among the many equally grammatical alternatives? What is it about common conventional word strings that makes them peculiarly resistant to the effects of aphasia?

As answers to these questions have emerged, it has become clear that the relationship between formulaic language and the language system as a whole has the potential to inform many applied linguistic endeavors, including language teaching, machine translation, author identification and profiling, artificial speech aids, linguistic rehabilitation, and perhaps even the early diagnosis of degenerative brain conditions.

Why Formulaic Language Exists

Processing Shortcuts

Psycholinguistic evidence strongly suggests that we operate under tight processing restrictions when handling linguistic material. If this is so, then our tendency to use formulaic language might be the result of expediency – that is, it makes processing shortcuts possible. Conceptualizing a 'processing shortcut' is highly contingent on how one models psycholinguistic knowledge. However, most psycholinguists would agree that the pressure point relates to assembly rather than storage. In other words, the brain seems very able to accommodate as many lexical units as we want to store, but we are very easily thrown off course when formulating an utterance, if we try to do too many things at once.

Quite why humans should experience difficulties in composing language online is unclear, but it is probably linked to our limited working-memory capacity. In one approach to psycholinguistic modeling, formulaic language is conceived of as a solution to this constraint. It bundles a grammatical configuration of several words into a single lexical unit that can be understood or retrieved without any grammatical processing. In fact, this proposal is seriously compromised, in its extreme form, by the fact that virtually no word strings are immune from some sort of grammatical fine-tuning. In its weak form, however, the model proposes that grammatical interventions are kept to a minimum, to the benefit of processing parsimony. That is, even if it is necessary to insert the subject, verb ending, and object into *do SOMEONE a favor*, a saving is still made over having to retrieve each word and ending separately and combining them from scratch.

Not all psycholinguistic models, however, easily accommodate the notions of ‘units’ and ‘assembly.’ Neurologically inspired models aim to identify the processes by which pathways of neural activity are established, maintained, and used. In such models it makes no sense to speak of a word string being ‘stored.’ Rather, a formulaic word string is conceptualized in terms of a fast processing pathway. Just as a pianist who practices a difficult sequence of notes will, by virtue of that repetition, find it easier to play in future, so it is reasoned that if you become used to producing the articulatory movements that result in a particular routine expression, then this pathway will be strengthened, until it becomes not only fast and reliable but also rather difficult to interrupt, modify or, if it should go wrong, put back on track without starting from the beginning again. Different approaches to psycholinguistic modeling make different predictions, and so are a useful focus for investigations. By testing the predictions of each model, their relative plausibility can be evaluated.

What Formulaic Language Is Used For

Promotion of Self

There are as many different proposals about the purpose of formulaic language as there are domains in which it is found. Under one or another name, it has been independently described across a wide range of areas of linguistic research, beginning, many centuries ago, with observations in the clinical domain, and most recently blossoming as a major focus of attention in second language acquisition and teaching. In between, attention has been paid to it by researchers working on child language acquisition,

sociolinguistics, literary style, phraseology, grammar, discourse, and psycholinguistics. Yet in each domain the purpose of formulaic language is differently conceived, so that a somewhat confusing picture emerges. Wray (2002) proposes that the explanation for the differences is that formulaic language is a generic strategic solution to a recurrent challenge for us as humans: how to promote our own interests.

The rationale for this proposal resides in the way that humans use language to manipulate others. Manipulation entails persuading another person to think, feel, or act in some way that you desire. Selecting linguistic material that enables you as a speaker to fluently express your message and enables your hearer(s) to easily decode it supports this self-promotional goal. For instance, commands in the army are given in a consistent, prespecified form, not only so that they will be instantly recognized, but also so that they will be acted upon as a reflex, rather than queried or challenged.

It is important to note that, in this context, it is not just the local meaning of utterances that the speaker wants the hearer to understand with ease, but also their meaning within the surrounding discourse and the pragmatic, social, and cultural context. Also, the speaker’s intentions may be altruistic at one level, such as when a teacher formulates the explanation of a concept in a way that will help the students understand it. But at a deeper level even such altruism is driven by the speaker’s desire to create a particular kind of outcome that is beneficial for him or herself. Teachers want to be good at their jobs and want to avoid having to explain the same things many times. The workman who shouts a warning to a passing pedestrian certainly wants to save him or her from danger but also does not want to be responsible for injuring someone.

The following sections examine some of the various functions of formulaic language that have been chronicled in the research literature. The proposed underlying agenda of self-promotion is just a hypothesis, and it is for future researchers to establish whether it stands up to scrutiny in each of the contexts in which formulaic language is believed to operate.

A Badge of Identity

Most native speakers can think of expressions that they have picked up from someone else. Sociolinguists have long recognized that humans use language as a tool for expressing their identity relative to other speakers. When we speak, we select particular turns of phrase that we perceive to be associated with certain values, styles, and groups. We are sensitive, too, to the choices that others make. Our linguistic choices

can be both conscious and subconscious and are part of a more general desire to behave like those with whom we most closely identify, or who embody our aspirations.

Social Bonding

Closely allied with the expression of identity is the selection of particular turns of phrase to achieve specific purposes in a (micro-)culturally acceptable way. For instance, in some kinds of Christian discourse, expressions like *praise the Lord* are used simultaneously as disjuncts conveying the speaker's stance towards the associated proposition(s) and as strong markers of the perceived shared values of hearer and speaker. At the macro-cultural level, native speakers within their broad speech community share certain knowledge about nativelike ways of expressing ideas – knowledge that nonnative speakers may not be party to. Becoming accepted into an adoptive speech community entails demonstrating this insider knowledge, though various dynamics relating to both the infiltrator and the host community may place obstacles in the way of a full match with native speaker knowledge.

Other kinds of social bonding also use formulaic language. For example, in Britain elaborate exchanges often take place during a simple sales transaction, with every stage accompanied by routine, largely unconscious, expressions of gratitude. Such behavior is evidently necessary to create and maintain the locally desired level of social ambience, for its absence can be interpreted as rudeness.

Memorization as an Aide-Memoire

One subtype of formulaic language consists of deliberately or inadvertently memorized material, including rhymes, prayers, speeches, songs, and so on. The deliberate memorization of texts is often associated with the need to recall the fine detail of the text correctly, not just its message or general form. It would be inappropriate, for instance, to remember only the gist of a Keats poem, so that one had to paraphrase it rather than recite it, for poetry is defined as much by the precise configuration of the form as by the meaning. Some texts, such as liturgical and legal rituals, have a performative status that can be nullified if the form is altered. Other texts must be recalled correctly because they are the key to other information. For example, it is important not to confuse which months have which numbers of days in the chant *Thirty days hath September* and not to reverse the order of the words in *Richard of York gave battle in vain* (used for remembering the colors of the rainbow), otherwise the very purpose of learning the text is defeated.

The mnemonic function of formulaic language matches well the psycholinguistic notion that a formulaic word string is retrieved as a single unit, or in some automatic way. The less processing that goes on, the lower the chances of making alternative choices that undermine the integrity of the whole.

But formulaicity really comes into its own where a balance is sustained between prefabricated text and creativity. This is in evidence in oral literary traditions, where the recitation of lengthy epic poems is achieved by the strategic use of repeated text patterns to express recurrent ideas. These provide a reliable structure for a unique performance event, in which the detail of the formulation is a one-off creative variation on a traditional oral text. Key research into formulaicity in oral performance was carried out by Parry (e.g., 1930) and Lord (1960) who compared traditional Slavic poetry performances to Homer's epics. But it has also been identified in many other cultures including Anglo-Saxon, Maori, and Tibetan. Closer to home, parents retelling well-known fairy stories display something similar. Each extemporization is unique, yet fully recognizable as a version of the original. Its form is constrained both by the plot itself and by traditional, thus more or less compulsory, turns of phrase (e.g., *I'll buff and I'll puff and I'll blow your house down; Mirror, mirror on the wall, who is the fairest of them all?; Who's been sleeping in my bed?*).

Fluency Under Pressure

Public extemporization, described in the last section, must count as a high-stakes activity that can put the performer under a lot of pressure. It seems entirely plausible that one function of repeated material in traditional narratives, as also the chorus in folk songs, is to provide the performer with processing space to remember and formulate the next part of the text. Formulaic patterns also support other kinds of fluent performance, such as auctions and sports commentaries (Kuiper, 1996). Here, as in epic poetry, familiar words and grammatical patterns aid not only the performer but also the audience. The performer can use well-rehearsed strings to relieve the pressure on productive fluency, confident that this material will come out effortlessly and without thought. Meanwhile, the audience, recognizing that a formulaic string has begun, can bypass full decoding and use the recurrent material as a means of locating and isolating what is new.

Support for First Language Acquisition

The relationship between formulaicity and language learning is complex. In first language acquisition

children are known to use memorized expressions, containing grammatical constructions that are precocious relative to their current level of linguistic knowledge. However, commentators often downplay this practice relative to the acquisition of single words and grammatical rules. The reason is that while formulaic language certainly plays a social and interactional role for most children, it is unclear to what extent the early holistic learning of word strings makes any contribution to the slower, more methodical learning of the language as a system of rule-governed unit combinations. Memorized strings do seem to be broken down and reused to some extent. However, the fact that children often ‘unlearn’ memorized irregular forms like *went* – only to have to relearn them later – has led many researchers to regard the breaking down of formulaic material as too patchy to be a major feature of language acquisition, leaving the role of the formulas something of a puzzle.

On the other hand, since a common feature of formulaic material, both in adult and child usage, is irregularity, it is somewhat to the child’s advantage **not** to be too precipitous about harvesting from a useful whole what might turn out to be rather less useful parts. In line with Peters’ (1983) notion of ‘segmentation,’ Wray (2002) has proposed that children and adults alike take a parsimonious approach to breaking down memorized word strings. This **needs only analysis** (Wray, 2002: 130–132) enables word strings to be associated with their holistic meaning until there is direct evidence for the possibility of variation in a particular locus, when the string will be loosened in just that place, to accommodate the variation. In this way, the idiom *by and large*, which never changes, is never broken down, because there is never any input that challenges its immutable form-meaning association. As a result, neither children nor adults inform their knowledge of the word *large* by referring to its occurrence in that idiom, any more than the meaning of *king* would be informed by its apparent occurrence in *barking*. In contrast, a word string such as *pull SOMEONE’S leg*, which displays limited variation, will establish a balance of fixedness to flexibility that accommodates the novel subject and possessor, along with appropriate verb morphology, but retains as fixed the occurrence of *pull* and *leg*. Needs only analysis, Wray argues, accounts for the conservation of irregularity in idioms and other formulaic word strings, and, being motivated predominantly by evidence in input rather than logical potential, also explains the relative rarity of many grammatically acceptable formulations for which another formulation already exists with the same meaning.

Help and Hindrance in Second Language Acquisition

In second language acquisition, new parameters result in new patterns (see Wray, 2002: Chaps. 9–11 for a detailed review). While young children seem to acquire a second language in a manner somewhat similar to their first (and with similar success), even at kindergarten age any differences in the uses to which the language is put (and in how the child perceives it as a communicative tool) seem to affect the pattern of acquisition. As children grow older, new psychological and social constraints appear to precipitate variations in learning style and outcome, as Wong Fillmore (1979) notably found in her study of five Hispanic children in California.

By adulthood, two broad tendencies can be observed. Naturalistic learners favor approximations of large chunks gleaned from input, which may remain permanently inaccurate in form, especially if they are effective in communication. Taught learners appear to undervalue phrasal input, focusing on smaller units in order to gain a sense of control in their expression and comprehension. By the time such learners are of higher intermediate level, they characteristically display grammatically logical but often nonnativelike choices. That is, they have missed out on the acquisition of ‘idiomaticity.’ The challenge of how to improve nativelike idiomaticity in intermediate and advanced learners is a focus of considerable research, but no easy answers have yet materialized. An irony of attempts to promote idiomaticity through the teaching of common nativelike expressions is that an excessive use of them can render a learner’s output a somewhat meaningless concatenation of phrases, disguising other aspects of his or her linguistic knowledge. As a result, the puzzle of how to teach nativelike language is matched by the puzzle of how to test it in relation to other abilities.

A Residual Lifeline

It has been known for centuries that certain kinds of common expressions, such as greetings and curses, along with memorized rhymes, prayers, and songs, often survive when a stroke or other injury disrupts a person’s linguistic abilities. In addition, individuals may produce one or more recurrent phrases peculiar to them and/or repetitive phonological strings with no apparent meaning. Psycholinguists are interested in establishing the properties shared by these resilient items, in order to shed light on linguistic processing in general. Meanwhile, clinicians and speech therapists focus on how someone with command of such a limited inventory of expressions can often succeed in conveying a great many messages, using intonation,

tone of voice, and voice quality to modify or cancel the customary meaning.

Recognizing Formulaic Language

Researchers of formulaic language are currently challenged by two major practical difficulties: how to define it and how to identify it in spoken and written text. These are inevitably intertwined, for you cannot find something that remains undefined, nor define it without having examples of it. Wray (2002: Chaps. 2 and 3) explores the issues in detail, showing that many definitions confuse form, function, and meaning, while others are too exclusive or inclusive to be useful.

Frequency

One approach is to define formulaicity as a function of frequency. In this view, word strings that are often heard and said gain processing privileges born of the repetition. The increasing ease of processing reinforces their preferential selection from among the options for expressing that message. Meanwhile, their frequency is what makes them sound familiar and nativelike, so that our desire to sound like those around us encourages us to continue selecting them for social reasons. The advantage for researchers of a definition based on frequency is that it facilitates reliable identification. One can set the parameters of an automatic corpus search and extract as formulaic all the material that reaches that threshold.

There are difficulties with this approach, however. Firstly with a very few exceptions – mostly idiom adverbials and adjectives like *by and large*, *spick and span*, and *lock, stock, and barrel* – formulae are not invariable in form and are often not contiguous either. This complicates the searching, and while wild cards can assist in the accommodation of certain kinds of variation, the setting of the search parameters remains a significant determinant of what is included and excluded in the output and how much manual sorting is subsequently required. A second problem is where to draw the line between two formulas and two variations of one. For instance, what is the relationship between *thank you*, *thank you very much*, and *thank you very much indeed*? In practice a contingency decision is taken. But by the time readers survey the results of a study, such decisions are often long forgotten, risking the proliferation of beliefs about absolute answers rather than definition-dependent ones.

A third problem is that frequency is not determined from a consistent baseline, but rather as a function of how often a message needs to be conveyed. When we find that *good morning* is more frequent in a corpus than *long live the King* this does not tell us

that the former is ‘more’ formulaic, only that people more often wish each other good morning than they wish the king a long life. Frequency searches therefore need to be able to measure how often a particular formulation is used to express its message. The formulaicity of *good morning* arguably owes more to its preferential use over alternatives like *good day* and *how do you do* than to its absolute frequency. Indeed, it might well be found that, opportunity for opportunity, *long live the King* is more predictable than *good morning*.

Form

Aligning formulaicity with grammatical irregularity offers an easy but rather narrow route to definition and identification. In more inclusive approaches, the cline of fixedness makes form-based definitions difficult to pin down. One strategy has been to make a feature of the variability itself, and place linguistic configurations along a continuum from fully immutable to fully flexible. Although many have favored this approach, it is difficult to avoid a descriptive taxonomy with no explanatory or predictive powers. Since there is evidently a dynamism about form, including the diachronic shift from flexible to inflexible (fossilized), this seems a pity. Nevertheless, it is clear that form cannot be ignored. Capturing the nature and extent of the variability has also been attempted, and entails the recognition of ‘frames’ composed partly of lexical material and partly of abstract categories representing closed or open class choices, e.g., *NP₁ take + TENSE NP₂ to task*. Many frames become predominantly abstract, once the potential for adjectives, intensifiers, and so on is allowed for, raising new theoretical questions about just how different such frames are from traditional linguistic descriptions.

Phonological form has attracted some attention, since fluency is associated with elision, weak forms, etc., and phrases with nonliteral meanings can be expressed within a single tone unit more easily than can their literal equivalents. However, it has proved difficult to find a resilient correspondence between pronunciation and formulaicity.

Finally, in form-based accounts, the status of standard collocations remains unclear. A word may preferentially combine with particular partners without being prohibited from pairing with others. The customary pairings are unquestionably idiomatic, but often do not have other features of formulaicity.

Meaning

Some linguists regard as formulaic only expressions with a holistic meaning that cannot be derived from the individual words. A useful test of this is to swap

an individual word with a near synonym, to see if this destroys some feature of the meaning. The results can be very informative: the *large intestine* is not the same as the *big intestine* nor the *big toe* as the *large toe*. However, it is easy to cross into instances where the alternative is not really a synonym. In *by and large* the word *large* does not, and never did, relate to size, and this is why **by and big* sounds impossible.

Holistic-level semantics is, however, not a sufficiently broad definer of formulaicity. Even if the definition is extended to cover the pragmatics of the whole, as with expressions like *have a nice day*, difficulties arise. The expression *great to see you again* will, for example, fall outside of the definition, being neither opaque nor endued with a strong pragmatic tone. A second difficulty is that there is no clear dividing line between what is and is not opaque. Several dynamics interact here, including the survival in a formula of an outmoded word (e.g., *curry favor*) and the use of metaphor (e.g., *straight from the horse's mouth*). Just as with morphology and etymology in word formation, what is opaque for one person may be transparent for another. It follows that any attempt to define formulaic language in relation to meaning cannot ignore the knowledge of the individual. Yet drawing on the individual's intuition and judgment as the basis for defining and identifying formulaic language runs into its own serious problems.

All in all, it remains difficult to characterise formulaic language in purely semantic terms, and, again, it is part of the researcher's job to formulate theory that can explain why this should be so.

Future Directions

Research into formulaic language draws together the theoretical and the practical. In applied spheres it is possible to by-pass theory, but understanding how formulaic language fits into the bigger picture remains important. So far, the modeling of formulaic language has been psycholinguistically inspired, but the role of psycholinguistic models in informing linguistic theory has always been debated. The point of contact must be the definition of the lexical unit, on the one hand, and of the word and morpheme, on the

other. Cross-linguistic research already questions the viability of the 'word' as a linguistic category (e.g., Dixon and Aikhenvald, 2002), and research on formulaic language suggests that words are not the largest units being manipulated by the grammar. While some theoretical linguists maintain that idiomatization falls outside the domain of formal linguistic description, there is undoubtedly scope for theory to address more directly the question of what formulaic language is and how it arises.

Foucault, Michel

T P Górski, Uniwersytet Wrocławski, Wrocław, Poland

© 2006 Elsevier Ltd. All rights reserved.

Michel Foucault (true name Paul, born on October 15, 1926, in Poitiers, France) was a French philosopher, psychologist, and psychopathologist. He graduated from the École Normale Supérieure de Paris in 1952. From 1954 to 1958 he taught French at the University of Uppsala in Sweden, and from 1958–1959 at the University of Warsaw, Poland, where he established the Center of French Culture. Foucault spent the following year in Hamburg, returned to France in 1960, and became the head of the Department of Philosophy at the University of Clermont-Ferrand. In 1969, he was given a professor title and was promoted to the Head of the History of Systems of Thought at the Collège de France. Foucault died on June 25, 1984.

Foucault's ideas developed in three periods marked by the issue of his major books.

The first period, represented by *Madness and civilization* (Foucault's doctoral dissertation) is inspired by the fact that madness, though originally inspired divinely, was considered a mental illness and thus simultaneously repressed in the Western societies. He also claimed that madness contrasted to sanity, and the repercussion caused by this distinction is a troublesome and scalding conception dating back to the Age of Reason.

In the second period of his development, Foucault issued *L'Ordre du discours*, which is a seminal study of the natural sciences, linguistics, economics, and social thought of the 18th and 19th centuries. Greatly inspired by Nietzsche's claim about the death of God, Foucault declares the death of Man – a discursive formation of the advances in sciences in the last 150 years.

During the last period (from 1975), Foucault examined the effects of power on the individuals and society, and demonstrated how historical inquiry are combined with philosophical questions about subjectivity, knowledge, and power. He showed how sexuality can be put into discourse and argued that simple liberation from power is impossible. Subjectivity, he claims, can be viewed through one's sexuality. In the immense three-volume study entitled *Histoire de la sexualité* (the first two volumes were issued during his lifetime; the third one is unfinished) he gives an insight into the understanding of sexuality through centuries, and how Western Societies perceived themselves as sexual beings.

Foucault juxtaposes the 'history of ideas' with the 'archeology of science.' In the 'speaking' of language, he sees the replication of discourses of power; what constitutes us as human speakers is social power, hegemony, and ideology. He claims that the history of thought, of knowledge, of philosophy, of literature seems to be seeking and discovering discontinuities. Foucault considers all knowledge arbitrary, including notions of truth, in order to keep power structures relevant and functioning. In this view, he rejects the linear model of history and suggests analyses of discourse, its relative rules in various moments of history, and sees any form of writing or expressing oneself as the way of abandoning of disruptions in favor of stable structures. Moreover, he sees discourse not as a document, but as a monument.

Foucault was not only philosopher, lecturer, and writer, but also participated in the political actions; he actively helped the Solidarność [Solidarity] party in Poland in 1980 and engaged in the movements against discrimination of the disabled, homosexual, and marginal social groups. His thoughts, taken over in the 1990s by the queer theory, became the source of the revival of the feminist, gay, and lesbian studies.

Frege, Friedrich Ludwig Gottlob

W A de Pater and P Swiggers, Katholieke
Universiteit Leuven, Belgium

© 2006 Elsevier Ltd. All rights reserved.

Frege was born on November 8, 1848, in Wismar, Germany. He studied mathematics at Jena, then at Göttingen, where he obtained his doctoral degree in 1873. He became Privatdozent at the University of Jena, where he taught mathematics. In 1879 he became extraordinary professor and in 1896 honorary professor. He stayed in Jena until he retired in 1918. He died on July 26, 1925, in Bad Kleinen. Frege's main field of research was mathematics and the philosophy of mathematics, but his lasting contributions are in the field of formal logic and philosophy of language. During his lifetime Frege, who was an introvert and had a very small audience, exerted little influence, but his ideas were diffused by Rudolf Carnap, Bertrand Russell, and Ludwig Wittgenstein. Because of the development of semantic theory and the growing impact of formal logic on linguistic theorizing, his work occupies a central position within contemporary semantic and linguistic theory, epistemology, and philosophical logic.

Frege's work can be seen as the (unfulfilled) realization of his logicist program, which consisted in reducing arithmetic to logic, i.e., in defining arithmetical concepts in terms of logical concepts and in developing a strictly formalist-logical system for arithmetic statements and procedures. His *Begriffsschrift* (1879) was the first important step in the realization of the program. Frege modernized propositional and predicate logic, and provided a notational system for expressing all types of relationships between propositions, and offered a formalization of first order predicate calculus. In his following book, *Die Grundlagen der Arithmetik* (1884), Frege provided a not-yet formalized elaboration of logicism. The main idea developed in this work is that numbers can be defined as classes of equivalent classes (hence the *a priori* truth of ' $2 + 3 = 5$ '). Frege then embarked upon the exhaustive formalization of his program, trying to reduce arithmetic to logic within an axiomatic system. This was the ultimate goal of his *Grundgesetze der Arithmetik*, the first volume of which appeared in 1893 and the second in 1903. But at the time the second volume was published, Frege had already been faced with a paradox in his logical system (the paradox was pointed out to him by Russell), and in spite of his efforts, Frege eventually had to recognize the unrealizability of his reductionist program.

In the process of working out his program, Frege had felt the need to explicate the underlying philosophical

views. This required a systematic reflection on notions such as truth, meaning, thought, concept, object, identity, function, and argument. Whereas the 'semantic theory' contained in Frege's *Begriffsschrift* was a poor one, he succeeded in articulating a comprehensive theory of meaning and reference in three articles published in the early 1890s: 'Funktion und Begriff' (1891), 'Über Begriff und Gegenstand' (1892), and 'Über Sinn und Bedeutung' (1892). Although the three articles were, in Frege's view, an informal study (oriented toward aspects of linguistic expression) meant to clarify the aims of logic (the study of laws and properties of thought), they belong to the foundations of modern philosophical logic. Frege himself continued to refer to these articles when, later in his life, he wrote three studies on thought and thought operations ('Der Gedanke,' 'Die Verneinung,' and 'Gedankengefüge,' published between 1918 and 1923). It is important to stress that Frege never referred to his logico-semantic views as constituting a 'philosophy of language' (in fact, as a logician he had a deep mistrust of natural language): whatever he wrote on meaning, reference, assertion, and on linguistic aspects of concepts and judgments was intended to be a less technical exposition of his work in the philosophy of mathematics and in formal logic.

Frege's theory of meaning (and reference) is basically the outgrowth of his reflections on the construction of a notational system for expressing relationships between objects and properties (for Frege's reductionist and very Platonicist ontology only objects and concepts are needed). Objects are expressed by names; as objects, Frege recognizes individuals, classes and truth values. Properties correspond to concepts, expressed by predicative words (*Begriffswörter*, or short: predicates). Predicates are instantiated by individuals (when these are subsumed under a predicate: *Socrates is human*), or are included in a more general predicate (subordination of a predicate under another predicate: *Humans are mortal*). Thoughts (*Gedanken*) are the result of a combination of (object-)names and predicates; they are expressed in sentences, which have a truth value. Predicates are treated as functions to which arguments are linked: a predicative 'function' leaves open one or more places that can be taken in by 'arguments', the variable semantic and syntactic terms filling in the open spots: *speaking* (x), *murdering* (x, y) as semantico-syntactic frames for propositions such as *Brutus is speaking* and *Brutus murdered Caesar*. So Frege treats basic propositional structure in terms of function and argument(s); he was very critical of the traditional analysis into subject and predicate, as it makes no distinction between subsumption and subordination. For the description of the structure of

propositions involving operations on the basic function-argument frame, still other expressions are needed, such as ‘propositional connectives’ and ‘quantifiers’ (also dealt with by Frege). Frege was aware that apart from assertive propositions or statements there are other types of sentences: commands, wishes, exclamations, etc. He excluded these from his logical investigations, and in fact seems not to have taken much interest in what he called the *Kraft* (‘force’) of linguistic expressions.

As a logician, Frege stuck to the principle of the part-whole correlation, applying it to the analysis of propositions (in direct relation to their truth value); later, this principle was called the ‘compositionality’ principle. The principle is used to account for the fact (1) that the truth value of a proposition results from what its component parts stand for; (2) that the (semantic) content of a proposition results from the combined contents of its component parts; (3) that we can construct new propositions out of (significant) parts of formerly uttered propositions.

The crown jewel of Frege’s ‘philosophy of language’ (essentially a logical semantic theory, with a syntactic component later developed by Carnap as ‘logical syntax’) is his theory of *Sinn* and *Bedeutung*. The terms have been most often translated into English as ‘meaning’ resp. ‘reference’ (but also as ‘sense’ resp. ‘meaning’); however, *Sinn* is not strictly (lexical) ‘meaning’ and *Bedeutung* is not only ‘reference’ (i.e., a relation) but also ‘referent’ (i.e., an object: the *Bedeutung* of a proper name is, in Frege’s view, the object denoted, and the *Bedeutung* of a proposition is its truth value) and even ‘importance’ (Frege’s semantic theory has an axiological ring to it, since he also speaks about ‘value’). The distinction – which Frege applied to proper names, to (uniquely referring) descriptions, and to (simple/complex) sentences (conditional sentences; indirect speech) – serves to set off (a) the objective idea corresponding to the way an object is presented to us [= *Sinn*] as distinct from all kinds of subjective representations [= *Vorstellungen*] that we can associate with an object; and (b) the object (a referent, class of referents, a truth value) in which the reference achieves its realization [= *Bedeutung*]. Identity statements (such as *The morning star is the evening star*) precisely are cognitively (scientifically) important, because through them we learn that two expressions giving a different presentation of an object refer to the same thing (in this case, the two expressions or names *the morning star* and *the evening star* ‘coincide’ in the same object, namely, the planet Venus). Of the same object various ways of

presentation can be given (like ‘Marcus Tullius’ and ‘Cicero’ or of Napoleon: ‘the winner of the battle at Austerlitz’ and ‘the emperor defeated at Waterloo’); the same *Sinn* or way of presentation can, at different moments, correspond to different objects (‘the president of the United States’). Although problems remain with the distinction (e.g., what is the *Sinn* of a proper name? How can one make a clear-cut distinction between objective ideas and subjective representations about objects?), Frege’s theory of *Sinn* and *Bedeutung* has been of crucial importance for the later study of meaning and reference (specifically for the analysis of proper names and descriptions) and for the logical analysis of sentences. Frege’s logic (and reductionist ontology) also inspired later work in logical syntax and semantics as applied to the analysis of truth and to the construction of an ontology.

Freire, Paulo

A Pérez Pereiro, Arizona State University, Tempe, AZ, USA

© 2006 Elsevier Ltd. All rights reserved.

One of the most influential educational thinkers of the 20th century, Paulo Freire became a powerful symbol of the relationship between education and social change, particularly in the Third World. Freire was born on September 19, 1921, in the city of Recife in northeast Brazil, where he grew up in poverty. He succeeded in entering a private high school with a scholarship and became sensitive at an early age of the discrepancies in power and wealth between Brazil's social classes.

Freire entered the University of Recife Law School in 1943 but decided that he should devote himself to education instead. He became the director of education at SESI (Social Service of Industry), a government agency responsible for improving the living standards of workers. He received his Ph.D. in 1959 from the University of Recife with the dissertation 'Present day education in Brazil.' During the 1960s, he became involved in movements for popular education, focusing on adult literacy in rural communities and, in 1963, became the director of the National Literacy Program.

Since at the time literacy was a prerequisite for voter registration, Freire's activities were considered overtly political and, by many in the ruling elite, subversive. In 1964, a military coup ousted President Goulart, and Freire was arrested and held for 70 days on charges of treason. What followed were 16 years of exile. During that time, Freire worked at the Chilean Institute for Agrarian Reform until he took a post at Harvard for a year (1969–1970) and then moved on to Geneva, where he became the educational director of the World Congress of Churches, traveling the world to promote literacy programs and develop further his ideas on education and literacy that he had described in his *Pedagogy of the oppressed* (1972).

A passionate Christian and a Marxist, Freire saw education both as a tool by which ruling classes

subdue the masses and as a way of resisting that very oppression. Freire attacked the 'banking' system of education, where the student is viewed as an empty receptacle to be filled with facts, and instead advocated a dialogic or problem-posing approach to teaching, where education is made meaningful because it is related to the real lives and experiences of the learners. The purpose of this style of teaching and learning is to empower learners by making them aware of their own capacity to transform the world. This process, known as conscientization, has been associated with Freire's philosophy of education, although he himself thought the term was often misused.

In 1980, Freire returned to Brazil and began teaching at the Catholic University of São Paulo and the State University of Campinas. He also continued to be involved in adult and mass education programs. In 1986 Freire received the UNESCO Prize for Peace Education, and in 1988 he was appointed minister of education for the city of São Paulo. Paulo Freire died on May 2, 1997, at the age of 75. His work continues to exert a profound influence on educational thought and practice to this day.

Gender and Language

M Talbot, Nottingham Trent University,
Nottingham, UK

© 2006 Elsevier Ltd. All rights reserved.

The field of language and gender is multidisciplinary in scope. Practitioners can be found not only in linguistics and gender studies but right across the humanities and social sciences, including in anthropology, cultural studies, education, literary studies, social psychology, and sociology. The point of contact is feminist interest in language and, in that sense, there is always some form of political agenda and engagement. After thirty years, the accumulated research is now wide-ranging. Explicitly feminist in focus are explorations of gender positioning, in representations in media broadcasting and print, and in interaction in the media and other institutions. To give an indication of the range of coverage, a few examples are: examinations of the dynamics of classrooms privileging boys (e.g., Swann, 1992); case studies of women in public life (e.g., Walsh, 2001); the wisdom and efficacy, or otherwise, of institutional guidelines on non-sexist language use (Cameron, 1998a); sexism in press coverage, e.g., victim-blaming in rape reporting (Clark, 1998), and the reinforcement of normative gender positions in reporting on a sexual harassment conviction (Talbot, 1997); the rhetoric of physically abusive husbands and the disenfranchisement of their wives (Adams *et al.*, 1995). Less explicitly feminist, but nevertheless coming from a feminist standpoint are studies of the minutiae of conversational interaction between close friends in same-sex groups (e.g., Coates, 1996), a study of bilingual youth culture (Pujolar, 2000), and many and varied storytelling analyses: of accounts of pregnancy (Freed, 1996), socialization of children at family dinnertables (e.g., Ochs and Taylor, 1992), lesbian coming-out stories (Wood, 1999), among many others. *The handbook of language and gender* is a detailed overview of the field, providing a full and indicative representation of its diversity and depth (Holmes and Meyerhoff, 2003).

Since the early 1990s, two prominent issues in language and gender have been: a sustained critique

of 'gender differences' as the research agenda and a need for firmer theoretical grounding. The sections that follow address both of them in turn.

Querying the 'Gender Differences' Agenda

There is a well-known claim that men and women use interactional styles associated with power and solidarity, respectively (*see Power and Pragmatics*). The existence of distinct female and male interactional styles has now gained widespread acceptance, to the extent that they have entered popular 'common sense' (cf., e.g., Talbot, 2003). There is a considerable weight of evidence to support this view, including research on politeness (e.g., Holmes, 1995) and on physical alignment and eye contact in conversations (e.g., Tannen, 1990). In a detailed study of compliments and compliment responses, for example, Janet Holmes has found New Zealand women using compliments a great deal more than men do, with compliments between women being used to consolidate solidarity between the giver of the compliment and the recipient. Holmes found that men, on the other hand, tend to find compliments threatening and may use mock insults and sparring to cement friendships instead. The overall picture is one of polarization; of men's talk as power based and competitive, women's talk as solidarity-based and cooperative.

According to the 'difference' framework, gendered language patterns are a consequence of distinct female and male subcultures. In this view, women and men behave differently because they are segregated in childhood. Boys, who tend to play in large groups with hierarchical social structure, learn to value status and become power-focused; whereas girls, who tend to play in small groups of 'best friends,' learn to value intimacy and become solidarity-focused. In the process, children acquire different gender-appropriate behavior. They enter adult heterosexual relationships with differing expectations about friendly interaction and consequently encounter problems of miscommunication (e.g., Tannen, 1991). These miscommunication problems have been presented as analogous to cross-cultural miscommunication.

There are many detailed critiques of the 'difference' framework (e.g., Cameron, 1995; Crawford, 1995; Freed, 1992; Talbot, 1998; Troemel-Ploetz, 1991; Uchida, 1992). The foremost concerns are the erasure of power and a tendency to overgeneralize, brought about by disregard for contextual considerations other than gender. Sex segregation in childhood is greatly exaggerated (Thorne, 1993). Claims about miscommunication among adults disregard issues of conflict over rights and obligations in times of social change (Cameron, 1998b). 'Gender differences'-based research on language depends on untenable dichotomies; critics have argued for far more nuanced understandings of power and solidarity, and indeed gender, and query the continued usefulness of the whole line of inquiry. The question: 'how does the language of women and men differ?' is no longer considered an appropriate starting point for research into gendered patterns of behavior seeking to further a feminist understanding of patriarchal social relations and sexual inequality. It is a question that assumes its answer lies with, precisely, differences. In short, the search for 'gender differences' has become an impoverished framework that flattens out the enormous range, variation, and richness of interaction between women and men, boys and girls.

Beyond 'Difference': The Poststructuralist Turn

In an article reflecting on the history of the field, Barrie Thorne points to a skewed emphasis on the micropolitics of face-to-face interaction – at the expense of the social structures and processes in which all face-to-face interaction is embedded – and accounts for it in terms of a 'strategy of deliberate one-sidedness' advocated by Erving Goffman (1983) (see Goffman, Erving). This analytic move generated a rich body of work on gender in everyday interaction but also, Thorne argues, generated a rift between theory and analysis (Thorne, 2001). Since the early 1990s, attempts to resolve this rift have drawn on critical theory, particularly poststructuralist theories of discourse and identity. A conceptualization of identity as flux is notable in recent research, strongly influenced by poststructuralism and paralleling developments in related fields (e.g., see *Critical Discourse Analysis*).

A poststructuralist position on discourse and identity provides an alternative to the polarized conceptualization of gender identity. While the 'gender difference' approach operates with a static conception of distinct male and female identities, developed and fixed in childhood, in a poststructuralist account identity is much more fluid. Feminist criticism from this perspective takes language as the site of the

cultural production of gender (e.g., Weedon, 1997). In this view, gender identities are not pre-given, but constructed in discourse; individuals take up positions in their enactments of discourse practices. This view serves to caution against making *a priori* assumptions about gender identity, such as by implicitly setting up a masculine-feminine dichotomy as the starting point (by determining to look for 'differences' in the behavior of women and men). It also serves as a corrective to assumptions of homogeneity in the social identities and relationships of women and men. Research influenced by poststructuralism examines not gender difference but the construction of gender identities. This approach to language and gender is grounded in the assumption that subjectivity is constituted in discourse. In discourse, individuals are positioned as social subjects who are gendered in specific ways.

Careful avoidance of bipolar categories of gender, and the comparative approach that goes with them, is a characteristic of recent research. Some analysts are explicit in their grounding in feminist theory (e.g., contributors to Hall and Bucholtz, 1995; Bucholtz *et al.*, 1999) and directly or indirectly interrogate categories such as masculine, feminine, heterosexual, white, middle-class, etc. 'Exceptional speakers' (the title of Kira Hall's contribution to the *Handbook of language and gender*) are increasingly studied on their own terms, rather than as exceptions to an over-rigid model that is unable to accommodate them. Such cases of 'footnote deviance' (Holmes and Meyerhoff, 2003: 354) include the 'tomboys' and 'sissies' that a 'two-cultures' account cannot accommodate adequately, and the African-American women whose verbal behavior awkwardly refuses to fit the pattern for a 'feminine' interactional style based on middle-class white Americans. This attention to liminal users of language has produced new areas of interest within the field of language and gender, e.g., an emerging field centering on 'the sexual and gender deviance of previous generations' (*ibid.*), which its practitioners have given the name 'queer linguistics' (see *Queer Talk*). A related point is that there are parallels between developments in the study of gender and of ethnicity, where the converse is taking place. A shift in focus to gendered subjectivity has generated increasing attention to masculinities. Just as whiteness is receiving critical attention, rather than occupying an invisible position as the 'non-ethnic' norm, so masculinities are being examined as constructed identities. Language and gender has seen significant expansion to encompass sexual orientation, ethnicity, and multilingualism, and, to some extent, class, involving analyses of spoken, written, and signed gendered identities (see *Intercultural Pragmatics and Communication*).

Gender and Political Discourse

L Martín Rojo, Universidad Autonoma de Madrid, Madrid, Spain

© 2006 Elsevier Ltd. All rights reserved.

Little research has been done on the topic of gender and political discourse, although this issue may show us the extent to which a gendered division of power

holds worldwide. (The recent work done by Walsh 2001 is noteworthy in this field.) While highly revealing of the key role that language and other styles of communication play in the political arena, investigations of gender and politics also shows how social closure occurs, hindering access and skewing the representation of certain genders, classes, and social groups in this area.

This article will deal primarily with issues of institutional politics, particularly parliamentary, legislative, and government politics, and not with issues of everyday politics. The very lack of women in government and parliaments explains in part the lack of research done on gender and political discourse (in Peterson and Sisson Runyan, 1993, conclusive figures from all continents around the world can be found. Also see Wodak, 2003). In fact, most countries that acknowledge the objective of promoting equality between women and men do not have parity governments, and only in a very few exceptional cases do women even comprise 40% of parliament. The fact that women's social position is not as strong as men's, despite progress made in certain areas of the world, has been linked to masculinist hegemony, which in turn is connected to social class and ethnic differences in different ways in different places. Masculinist hegemony is diffuse since, as Walsh (2001: 17) indicates "it is embedded in impersonal discursive practices and institutional structures that are historically associated with men." Indeed, when statistics are broken down by gender in the areas of education, health, economic participation, or wages, women as a group are still at a disadvantage. The fact that women's social position remains weak, although to varying degrees in different countries around the world, explains why women encounter resistance and difficulties in joining the political sphere and other prestigious areas of society such as business or academia. In the legitimization of this social weakness, several factors seem to play a significant role, like religion (Balaghi, 1994), culture (Graumann-Ubale, 1996), or historical reasons (Dudink, 2004).

Because our societies perceive a process of evolution and modernization leading women's presence to increase daily throughout the world, their greater presence in the Western sphere, considered to be more 'evolved' ('civilized'), is considered a given. Nevertheless, these assumptions are not always justified and mask some important aspects of the issue. For instance, while the female participation rate in northern European countries stands out as an exception (Gomard, 2001), other countries considered to be less Western or civilized, such as Costa Rica and Rwanda, apply the quota system.

Seemingly, only where strong women's movements conjugate certain political clout with the defence of women's social position and interests can political change increase women's numbers in politics. Thus, the political earthquake hitting Rwanda or Northern Ireland has uniquely placed women's movements actively participating in the peace negotiations and making noteworthy contributions to national reconciliation. These women have subsequently stood for public office in elections in order to change

policies. Analogously, the processes of political decentralization in Spain and recently also in the United Kingdom, have enabled the conditioning of women politicians in regional parliaments and governments, and in regional governments (thereby enabling the recent constitution of a parity national government in Spain with women who have demonstrable experience in government).

Such examples seem to indicate that barriers encountered by women are so frequent and substantial that the process is sometimes not gradual (as it seems to have been in Scandinavia). At times, the political rules are modified, opening the way for women only after deep change altering the political equilibrium, or even only after strong social upheavals. But the figures are overwhelming and leave little room for optimism. The results of deep changes in the political rules, if they do suffice, are not always positive. Developments in the so-called Eastern European countries illustrate how political change can lead to lower female participation (Hungary, Poland, Rumania, and Russia are clear examples. See Peterson and Sisson Runyan, 1993: 54ff.; see also Matland, 2003). Seemingly therefore, only where strong women's movements conjugate certain political clout with the defense of women's social position and interests can political change increase women's numbers in politics.

This article reveals how language barriers (i.e., difficulty in attaining an education and socialization generating an acceptable communicative style for intervening in the social arena), and cultural barriers (i.e., difficulty in fully participating in traditionally male-oriented fraternal networks within political organizations), are rooted, but also reinforce structural barriers (particularly, the unequal distribution of women and men in the public sphere of politics; differences in women's socialization that do not prepare them to overcome cultural and linguistic barriers, etc.).

In order to show these links, the first section of this article analyses the issue of gendered communicative styles, the difficulties they present for women, and what women contribute by modifying traditional patterns. Section two demonstrates how perceptions of gendered communicative styles affect the way women involved in politics are represented and evaluated. Finally, section three examines the role played by the current discursive order in reproducing gender inequality and how language barriers are linked to other cultural and structural barriers.

The Discursive Order: Is There a Feminine Style in the Political Arena?

Several of the authors who have worked on this issue have used 'communities of practice' as their starting

point to suggest that the political domain constitutes a discursive order characterized by certain ways of speaking and evaluations about their appropriacy that are traditionally associated with males. That is, professional politicians are seen as an “aggregate of people who, united by a common enterprise, develop and share ways of doing things, ways of talking, beliefs, and values, -in short practices” (Eckert and McConnell-Ginet, 1999: 186). The fact that this community of practice has traditionally been made up of males explains why such ways of speaking and values have taken shape as dominant and why everything departing from this practice and these values is appraised as unsuitable or unacceptable. While no specific communicational style is demanded of men in the political arena, women do not seem to have an appropriate one available. This inequality in demands leads to a process of exclusion, making it difficult for women to gain access to important resources and positions in the organization. This situation is an example of social closure (social domination).

This exclusion may, in turn, give rise to a situation in which access to these high-level resources and positions is achieved by means of adaptation to the dominant styles and forms. Within research on language and gender, certain linguistic choices have been identified as masculine in style: being more assertive in one’s expression and exercising of power (which includes highlighting rather than concealing responsibility for decisions or actions), and being direct and confrontational with adversaries in political debates. These traits, which are not necessarily found among all males, appear most clearly in two specific spheres in the political arena: in parliamentary debates and in the creation and maintaining of fraternal or peer networks, both within political organizations (parties and unions), and in informal interaction between members of the same or of different parties. Ties are made and negotiations take place outside a formal context through these networks, making them as important in politics as they are in other areas.

These masculine stereotyped forms are increasingly rejected by women. Thus, within the British Labour Party, for instance, Harriet Harman has criticized what she terms the “militaristic” and “macho” language of the laddish coterie who surround Blair, claiming that talk of “big guns,” “big hitters,” and “big beasts” is not how women refer to one another (the *Guardian*, 9 March 1999; also see Walsh’s analyses, 2001: 100ff.). However, these discursive practices are highly effective in building fraternal networks in political parties.

Researchers have also attempted to define the traits characterizing a feminine style. Authors such as Blankenship and Robson (1995), using a study of a

corpus of political discourse in the United States between 1990 and 1994, have identified the following five traits: basing political judgments on concrete, lived experience; valuing inclusivity and relational nature of being; conceptualizing the power of public office as a capacity ‘to get things done’ and to empower others; approaching policy formation holistically; moving women’s issues to the forefront of the public arena.

At least the first three of these five traits have been considered paradigmatic examples of how women tend to tackle communication in other public spaces, such as business. However, as with all characterizations of feminine styles, we can never be sure whether these styles actually appear in women’s discourse or whether they are rather a perception or a representation of women in social positions of responsibility, based on and shaped by gender stereotypes (Martín Rojo and Gómez Esteban, 2002, 2004).

Lastly, we cannot overlook the different ways in which women devoted to politics act. In fact, Walsh (2001: 11) identified three models explaining these differences. First is the accommodation model, required by a male-oriented cultural context, in which women adapt to dominant practices both in their management of conflict and in their expression of authority. Nevertheless, adapting to molds and forms traditionally considered typical of male politicians often leads women politicians to be seen as strange specimens, behaving as would be expected of a leader, but not of a woman (Margaret Thatcher is a paradigmatic example). The fact that women to whom this categorization is attributed are seen as exceptions does not contribute to promoting the feminization of the political sphere.

The second model is what Walsh terms the critical difference model, which could be characterized as the search for cooperation instead of adopting an aggressive, confrontational style. Here, there is a risk of being perceived as weak and ineffectual, or to put it bluntly, as poor professionals having arrived where they are thanks to the paternalism of males who have given them an undeserved place due to quota policies (this phenomenon could be seen as similar to what occurs in leadership positions in the sphere of labor, cited by authors such as Holmes, 1995; Tannen, 1996; Martín Rojo and Gómez Esteban, 2002, 2004). As indicated by Deborah Cameron (1992: 76), regardless of how this style is judged, adopting it contributes to rectifying the traditional dichotomy between private and public spheres and the unequal distribution of women and men in these spheres. It could be expected, however, that with the gradual feminizing of the public sphere, adopting this style would contribute to transforming the rules and values that govern it.

The third model is what Walsh calls the performative model and consists of women switching between the other two models depending on the communicative situation and other factors. Although this model is perhaps the most widely followed (see Romaniuk, 2004 for similar conclusions), it remains invisible. As stated in Fairclough's (1989: 182ff.) analysis, although Margaret Thatcher herself used a hybrid style, carefully conjugating selected features associated with middle-class femininity and 'authoritative expressive elements' used by men politicians, the masculine model was insistently attributed to her (she was described as 'the best man in the cabinet'). Her model was even resorted to in order to masculinize and discredit the work of other women (Walsh cites the case of Margaret Beckett when competing for Labour leadership in 1994 (Walsh, 2001: 72–73).

This frequent alternating of styles does not depend so much on a rational choice made by these women but is rather a reflection of the tension they experience, leading them to use different options. Examples such as the new President of the Parliament of Andalusia, who declared her will to exercise her power "not to follow in the footsteps of men, but to open new paths on which womens' footsteps may be seen..." are still few and far between. In addition, as Wodak (2003) points out, female MPs in EU parliament display a wide range of identity constructions, and gender can be overridden through national and ideological affiliation.

Furthermore, while serving as an avenue for women to develop their own style of leadership, stressing the differences between the masculine and feminine forms of exercising power also involves risks. Emphasizing some aspects of what has been defined as specifically feminine leadership, or defending its virtues, may in fact serve only to further stereotype and marginalize women in leadership and politics. It is also paradoxical that this marginalization comes at a time when certain cracks can already be seen in the towering edifice of the two-sex and two-gender system. (Given that people are now more aware of the fact that gender differences are socially constructed, distinctions between the genders have weakened and a host of different ways to be a woman or a man are expressed more freely.) (Freed, 2003). And what is even more highly suspicious is the vulgarized version of the positive view of differences in academic circles that is so prevalently found in the media, the self-help industry, and books on popular psychology. *Cosmopolitan* has made an effort to tie these different ways of speaking with the presence of certain hormones or the different constitution of our brains. Through dichotomies

and oversimplification, these media relentlessly stress that women and men shop, think, speak and behave differently.

Beyond any doubt, in the current discursive order of politics, we find that the requirements are somewhat flexible and open for men (if male politicians adopt a nonconfrontational style, this behavior would not be necessarily interpreted as a sign of weakness), but restrictive for women who are also harshly criticized and often excluded from a sphere where dominant practices have been imposed throughout history. We therefore find ourselves up against an example of domination and exclusion that is reproduced and bolstered by discursive practices. From this perspective, at least three areas stand out for their importance: parliamentary debate, government tasks, and peer relations in nonformal contexts. The first area is linked to the adversarial style, the second to how power is expressed and managed, and the third to building one's own identity and one's own group identity.

As indicated by other authors (Puwar, 1997; Sreberny-Mohamadi and Ross, 1996; Walsh, 2001), women find a confrontational style, ranging beyond parliamentary debate, to be alienating and inhibiting. As Sedgemoor (1995: 54) indicated, in parliament, when differences are small, they must be magnified and when they do not exist at all, they must be fabricated.

However, cultural differences can be observed in how this confrontation is managed. In the British parliament, for instance, both the parliamentary procedure and the physical layout itself stimulate confrontation (Sedgemoor, 1995: 54). Legal interventions are allowed in debate where one speaker gives way to another so that he or she can make remarks that tie in with the line of argument. These legal interventions are not permitted in other parliaments. But illegal interventions, highly effective in increasing the aggressive tone of the debate, are found in all parliaments. When made on a group basis, these interventions consist of interjections, stomping, noise, and all types of comments demonstrating support or disapproval of the speaker, while on an individual basis, illegal interventions usually consist of comments such as 'that's a lie' or 'resign.' In this light, Shaw's figures (2000) illustrate that legal or illegal interruptions in parliamentary debates are often made by men. By not availing themselves of these interventions, women therefore limit their access to the floor and thus relinquish their power in the debates.

In the second area, government tasks, the way is gradually being paved for new styles of leadership incorporating more cooperative and less assertive

traits that afford greater scope for interpersonal relationships. Yet these innovations come up against resistance even when advocated by men. (As compared with his predecessor's brusque, pushy, severe style, Spanish prime minister Rodríguez Zapatero has been dubbed 'Bambi' by the opposition for his conciliatory style). This resistance is even greater when it comes to women, since their practices, based on an ideology that understands power as a resource to transform society and not to dominate others, are not considered to be chosen rationally but rather considered to be a sign of inherent weakness. In her campaign within the British Labour party, Beckett's reluctance, for instance, to speculate on potential situations in which she would push the nuclear button were not understood as a political position in itself, i.e., the rejection of a populist discourse on security, or support for nuclear disarmament. Instead, they were understood as a sign of weakness invalidating her as a candidate.

Lastly, in the third area, peer relations, the role played by practices traditionally associated with masculine forms is interesting to observe. Especially interesting is the role they play in informal contexts (coffee breaks, mealtimes, parties, Christmas dinners, nights out), where relationships become less formal, power relationships are less manifest, and more stable networks emerge. Organizations and political parties are built on these types of relationships. Paradoxically, obstacles are also presented for women in participating in this type of situation, especially in highly masculinized sectors. It is important to draw attention to the social implications of this marginalization of women in male peer networks, since at the higher levels of organizations real power resides in these groups. Because networks like these are the basis for choosing the candidates called upon to represent the people in elections, these relationships play a key role in either promoting or thwarting women's inclusion.

Reducing political relationships to 'gentlemen's clubs,' 'big guns,' or 'political babes' excludes those who explore new, more democratic types of political systems. Therefore, analyzing the barriers to women in politics better enables us to show the potential results of women's equalitarian participation in politics that could, in turn, open up the possibility of new ideological positions. It has, for instance, been noted that women's role in peace negotiations after various conflicts in Northern Ireland, Rwanda, or Israel-Palestine has opened up forms of reconciliation that are not based on excluding any of the parties. Also, the awareness of being in a position of weakness in politics can lead to a less assertive style and the seeking of consensus in decision-making and exercising power. Moreover, women's involvement in grassroots

movements is bringing about new brands of politics that are closer to people's everyday life experience and needs. This less elitist style, more adapted to voters' specific situations, means that politics becomes much more democratic. Romaniuk (2004) also shows the emergence of a new communication ideology that values private forms of communication in the public sphere. It has also been indicated that women are less susceptible to corruption (according to John Mathiason, former Director of the UN Division for the Advancement of Women), perhaps because of their exclusion from the fraternal networks where so many things are negotiated outside the regulatory sphere of the political arena. Lastly, women's role in changing the political agenda seems noticeable, although it is done from NGOs, since in certain countries, consensus has been reached between women of different political parties to address issues such as abuse of women, or to respond to some of the claims of the women's movement's.

The Social Representation of Female Politicians

What we have seen thus far shows how the style adopted by women in positions of power in government or parliament is sometimes not as important as how these styles are perceived and represented. Several authors have studied how representations reproduce gender stereotypes and traditional dichotomies separating the public and private spheres.

The media play an important role in reproducing and disseminating dominant representations of women involved in politics (Ross and Sreby-Mohammadi, 1997). One of the main reasons, in addition to the deep rooting of traditional visions indicated by Walsh, is that most of those who own or control the media are men who assume that the ideal reader will also be male.

Due to the strong impact of gender inequalities in the distribution of social spaces, women's presence in the public sphere is still viewed as exceptional. Thus, as Fowler (1991) indicated, male presence undoubtedly overshadows female presence in the British press, which reaffirms women's underrepresentation in the public sphere (King, 1992: 133), feeding the lack of female models. The few articles which are devoted to women reproduce traditional stereotypes, that is, these articles include references to women's family ties (husbands, fathers, children, etc.) or provide information on their marital status, thereby reaffirming their image as dependent (on the will or actions of others). These articles often also include observations and value judgments regarding their physical aspect (for instance in the campaign for Labour

Party leadership “where Blair was a youthful 40-something, Beckett was post-menopausal” (*Daily Express*, 24 June 1994). Adjectives used to describe women usually place the emphasis on their physical and emotional qualities and nearly never on their professional or moral worth. And when the adjectives do evaluate their moral worth, they usually refer to traditionally imposed traits (fidelity, resignation, care for others) or traditionally disdained traits (domineering, masculine in style, wielding of ‘female weapons’). (McDonald, 1995: 50, points to double moral standards in social spaces.)

Therefore, when women’s action as high-level politicians is represented in the media, we find they are considered tokens, that is, as symbols of their gender rather than as individuals. For example, when a minister is criticized for her actions, her entire gender’s suitability for government is called into question, while a man’s incompetence only calls into question his own incapacity and never that of his entire gender.

Thus, as Kanter points out, when women are seen as token they are subject to three perceptual tendencies: greater visibility, contrast or comparison, and assimilation (1977: 130ff.). Greater visibility, contrast, and comparison can be observed in the scrutinizing and criticism of women’s action in government. Walsh (2001) has studied how women’s actions within the Labour Party, the Blair government (‘Blair’s babes’), and the Welsh and Scottish parliaments are continuously compared and benchmarked against male ways of speaking and values. Women in government are the marked gender (Tannen, 1996). As a result, their behavior is observed and judged for its suitability. If their performance is judged to be negative, then the whole gender is discredited. Suffice it to cite how Welsh Agriculture Secretary Christine Gwyther was treated in the media for being vegetarian.

This discredit leads on to the third tendency – assimilation. Women in the public sphere are seen as more masculine than in the domestic sphere. Thus, those women who do not convey an empty image of power are perceived as macho. This is not a positive representation, however, since they are seen not as women, but as rejected specimens. They are the iron ladies, the women who wear the trousers, pseudo-men (for research on virilization and exclusion suffered by these women in the public sphere see Martín Rojo and Gómez Estaban, 2002).

The observation of these perceptual tendencies leads us to reason that the women who do not take part in this dichotomized distribution of public and private spheres are the ones who pose the greatest contradictions and tensions in the media. Page’s

analysis (2003) of the representation of leading barrister and wife of the then British prime minister Cherie Booth Blair in the British press shows these contradictions. The stereotypically passive representation of Cherie Blair might be seen as securing her husband’s political status against the potentially destabilizing influence of her representation as a powerful professional in the public domain, thereby reinforcing gendered norms (Page, 2003: 570). What has yet to be studied is the impact of her representation as a professional on other working women. Here, Page’s analysis seems to show that while her professional worth is not questioned, she is considered to be an exception.

Barriers Constituting a Glass Ceiling and Potential Action

Language barriers hamper women’s access to politics both on an institutional and an everyday level in both parties and organizations. We must not overlook female illiteracy rates, higher than those of men throughout the world. While women have not yet been socialized to compete in the political arena, what is relevant is how in the current order of discourse the dominant practices and values deprive them of the tools they need to make a way for themselves.

We have already seen the dilemmas faced by women in politics as well as the dominant social representations in the media. While no specific communicational style is demanded of men in institutional politics (except some stylistic preferences for expressing conflict and opposition in debates and for exercising power), women politicians do not seem to have an appropriate style available to them. This inequality in requirements gives rise to a situation where both maintaining their traditional features and assuming traditional masculine traits leave women looking out of place in politics. As a result, men’s prevalent position in organizations is not threatened, but rather effectively reproduced and therefore bolstered.

In addition, while stressing the differences between the masculine and feminine forms of exercising power provides an avenue for women to develop their own style of leadership, it also conceals other restrictions they face at entry and the thwarting of new ideological positions and ways of doing politics.

Changing this situation requires changing discourse’s social order so that it is open to other types of participation. Carbó (2003) studies one outstanding example of the changes required, the Zapatist commander Esther’s intervention in the Mexican Parliament, the first by a nonparliamentarian, indigenous woman. Yet, we know that the order of

discourse cannot be modified unless other orders are. In fact, it is no coincidence that women have attained socialization in less competitive areas, like politics in regional parliaments and local institutions, because less power is wielded there (i.e., the autonomous governments in Spain and the United Kingdom) or in situations where overcoming crises has required innovative solutions.

Language barriers are inextricably tied to other barriers, particularly cultural ones, favoring particular practices and ways of doing politics. This link explains why women MPs in Britain were not even able to change the evening sessions in the British Parliament to make their work and home lives compatible. Their attempt was seen as a break with tradition, and the same holds true for their rejection of the dominant aggressive, masculine style.

Both cultural and language barriers invariably lead us to structural barriers, to the unequal distribution of social spheres, and to the relegating of women outside the most prized public sphere. Social changes are threatening this order but have not yet changed it. More deeply rooted and seemingly more difficult to change is the strong link traditionally established between power and masculinity. Gender stereotypes are still shaping role stereotypes in the political arena. As a result of the association of power and masculinity, when women reach high positions, they can be regarded as deviant examples or virilized women (Golda Meir and Margaret Thatcher are outstanding examples). This association between genders and roles promotes essentialist discourses attributing specific worth and possibilities. As a result, we see that the political arena is a gendered social space.

As long as women's numbers in politics are low, it will be difficult to see that the problems we face as women (abuse, less research on diseases affecting women, lower salaries, difficulties in attending to both work and children, etc.) are problems of society as a whole. In democracy, justice must be for the entire population. Women's greater presence in politics would help to bring these issues to the fore and would encourage solutions attenuating social exclusion and injustice.

Genre and Genre Analysis

Genre in Literary Studies

When, in the 18th century, English commentators wished to follow their classical predecessors, Plato and Aristotle, in distinguishing among types of artistic production, they borrowed the word *genre*, 'kind,' from French. The term was initially applied to literary texts, which had also been the concern of the classical commentators. All literary genres were considered to be recognizable by their adherence to conventions of form, content, and use of language. For example, Aristotle, in Chapter 6 of the *Poetics*, defined and described epic, lyrical, and dramatic poetry by identifying their constituent parts. Of tragic drama, he wrote (quoted in Dorsch, 1965: 39):

Necessarily... every tragedy has six constituents, which will determine its quality. They are plot, character, diction, thought, spectacle, and song. Of these, two represent the media in which the action is represented, one involves the manner of representation, and three are connected with the objects of the representation; beyond them nothing further is required.

In a similar vein, but over 2000 years later, the Romantic essayist William Hazlitt began his *Lectures on the English Poets* (1818 [1910]: 1) by focusing on the content, form, and phonological features of poetry:

In treating of poetry, I shall speak first of the subject-matter of it, next the forms of expression to which it gives birth, and afterwards of its connection with harmony and sound.

According to classical Greek literary theory, the distinction among lyric, epic, and dramatic poetry was found in their different use of narrative voice: In lyric poetry, only the narrator's voice was heard; in epic, the narrator spoke alongside the characters; and in dramatic poetry, only the characters' voices were heard. Despite a longstanding tendency among neo-classical commentators to treat genres as discrete and stable, writers inevitably mixed them; for instance, Shakespeare mixed prosaic comedy and tragic verse by following the murder of Duncan with the comic porter's scene in *Macbeth*, and in *Hamlet* (Act II, Scene ii), he parodied the critics of his time through Polonius's pedantic distinctions among the genres of 'tragedy, comedy, history, pastoral, pastoral-comical, historical-pastoral, tragical-historical, tragical-comical-historical-pastoral' and so on.

By Hazlitt's time, the proliferation of new genres, such as the novel, and the Romantic critic's preference for the unique and original over the generic and conventional led to the gradual decline of the importance of the concept of genre in literary studies. As a result, in literary studies and in other esthetic fields, such as art and film criticism, to describe something as a 'genre piece' was to stigmatize it, a process some writers and critics have been at pains to challenge (e.g., Braudy, 1985):

No part of the film experience has been cited more consistently as a barrier to serious critical interest than the existence of forms and conventions, whether in such details as the stereotyped character, the familiar setting, and the happy ending, or in those films that share common characteristics – Westerns, musicals, detective films, horror films, escape films, spy films – in short, what have been called *genre* films. Genre films especially

are criticized because they seem to appeal to a preexisting audience, whereas the film 'classic' creates its own special audience through the unique power of the film-making artist's personal creative sensibility.

In the 20th century, certain critics began to rehabilitate the concept of genre in literary studies. Rather than conceiving of genre as a fixed, absolute set of conventions, however, modern critics see genre as a dynamic set of conventions that are related to changing social institutions and purposes. Structuralist critics redefine genre as a set of expectations that a reader acquires from his or her reading. These expectations may be fulfilled or frustrated in any further act of reading, each one of which reshapes one's generic expectations. The literary critic's role, therefore, is not to state the formulas to which literary texts must adhere, but, at least in part, to expose the expectations that account for particular esthetic responses. The structuralist critic also tends to favor those works of literature that set out to challenge prevailing expectations through parody or denial, as Eichenbaum (1925; cited in Scholes, 1974: 88) noted:

In the evolution of each genre there are times when its use for entirely serious or elevated objectives degenerates and produces a comic or parodic form. The same phenomenon has happened to the epic poem, the adventure novel, the biographical novel, etc.

Eichenbaum argued that the genre is 'regenerated' through the playful subversion of conventions that enable the creation of new forms.

Genre in Language Studies

Structuralist critics view literature as a self-contained system with its own codes and conventions. In contrast, another major figure, Mikhail Bakhtin, related literary language to the wider and hitherto neglected system of codes and expectations governing discourse in general. In 'The Problem of Speech Genres,' Bakhtin (1952–1953 [1986]: 60) wrote:

Each separate utterance is individual, of course, but each sphere in which language is used develops its own *relatively stable types* of these utterances. These we may call *speech genres*. . . . Special emphasis should be put on the extreme *heterogeneity* of speech genres (oral and written). In fact, the category of speech genres should include short rejoinders of daily dialogue (and these are extremely varied depending on the subject matter, situation, and participants), everyday narration, writing (in all its various forms), the brief standard military command, the elaborate and detailed order, the fairly variegated repertoire of business documents (for the most part standard), and the diverse world of commentary (in the broad sense of the word: social, political). [*italics in original*].

In language studies, in the decades following Bakhtin, the term 'genre' has been appropriated by linguists who wish to explore nonliterary spoken and written discourse in which expectations of conventional use of text structure, lexis, and syntax are likely to be satisfied; for example, academic research articles, letters of application for employment, recipes, and so-called 'service encounters' in which customers interact with shopkeepers in order to purchase goods. Despite common interests, there is considerable divergence in why and how these linguists use the term 'genre' and undertake genre analysis.

Genre in Systemic-Functional Linguistics

Systemic-functional linguists employ genre as part of their project to relate language use to its social context, in particular, 'the context of culture.' Interest in genre arose out of a growing sense of the inadequacy of the concept of 'register' to account for the contextual aspects of text. Register analysis assumes that textual features can be predicted because texts vary conventionally in relation to three 'situational variables'; namely, 'field' (subject matter), 'tenor' (relationship between participants in the interaction), and 'mode' (whether the text is written or spoken). These situational variables did not deal with *why* the text might have been written or spoken. The realization that a text might be shaped and so categorized in relation to its communicative purpose led to a resurgence of interest in a text's genre; that is, how a text relates systematically to its context of culture.

For example, the register of entries in travel guidebooks might vary according to the writer's relationship with the intended readership (a formal relationship with erudite connoisseurs of, say, art history and architecture, or an informal relationship with student backpackers); the subject matter covered by the entries (fields such as food, wine, history, architecture, beaches, night clubs, and various types of accommodation); and the mode (usually written but possibly with some appeal to spoken discourse in the less formal realizations). None of these situational variables takes into consideration *why* tourist guidebooks come to be written; in other words, their context of culture. Analysis of the genre of travel guidebooks would consider the cultural phenomenon of tourism: the fact that different types of people choose to travel as a leisure pursuit in which they gaze at certain things (landscape, certain buildings), eat certain kinds of food, and indulge in particular leisure pursuits (swimming, clubbing, visiting galleries, shopping for souvenirs) before moving on. A consideration of the genre of a text helps account

for its content, as well as its form: A generic text is one in which conventional characteristics have developed out of an evolving set of cultural imperatives.

Systemic-functional linguists begin to analyze the genre of a text by assuming that its overall purpose is met through a sequence of stages, each of which achieves an intermediate purpose. The analyst seeks, through observation of a number of related communicative events, first to identify these stages and then to decide which are optional and which are obligatory, as well as their possible chronological order. Ideally, the analyst then arrives at the “generic structure potential” (Halliday and Hasan, 1989: 63–69) of a set of communicative events. Hasan recorded a number of ‘service encounters’ at a grocery, which yielded several apparently obligatory elements that she termed sale request, sale compliance, sale purchase, and purchase closure. These obligatory moves were sometimes combined with several optional elements. Hasan’s notion of generic structure potential involved a considerable level of detail. The elements were not only shown to be compulsory or optional but they were also put in predictable sequences and recursive elements were identified.

Though fewer of her successors dared to be quite so detailed in their formulation of generic structure potential, Hasan’s work was followed, for example, by Ventola’s (1987) crosscultural comparison of Finnish and Australian English talk in a post office and gift shop and by McCarthy’s (2000) discussion of talk in a hairdresser’s salon and during driving lessons. McCarthy’s study was particularly concerned with the interplay between the relatively predictable ‘transactional talk’ (which, in a hairdresser’s salon, included ‘arrival and checking in for appointment,’ ‘discussion of how the client’s hair is to be cut,’ and ‘payment/closure at desk’) and the less predictable ‘interactional talk,’ such as evaluative comments on the smell of the shampoo, the shape of the protective gown, or casual conversation about the hairdresser’s life and recent experiences. McCarthy argued that, though it is less predictable, the interactional talk is as important as the transactional, because it is the former type of talk that manages the client–customer relationship.

Unpredictability is an issue for genre analysis, and it is fair to say that much genre analysis favors conventional situations. Kress (1985: 19) went so far as to argue that most situations are conventional and, therefore, produce texts that can be characterized as ‘generic’:

The social occasions of which texts are a part have a fundamentally important effect on texts. The characteristic features and structures of those situations, the

purposes of the participants, the goals of the participants all have their effects on the form of the texts which are constructed in those situations. The situations are always conventional. That is, the occasions on which we interact, the social relations which we contract, are conventionalized and structured, more or less thoroughly, depending on the kind of situation it is. They range from entirely formulaic and ritualized occasions, such as royal weddings, sporting encounters, committee meetings, to family rituals such as breakfast or barbecues or fights over who is to do the dishes. Other, probably fewer occasions are less ritualized, less formulaic; casual conversations may be an example.

Despite Kress’s skepticism about casual conversation, McCarthy’s (2000) discussion of interactional talk and Eggins and Slade’s (1997) exploration of casual conversation suggested that casual talk is at least partly amenable to genre analysis. Eggins and Slade (1997: 229) identified, for example, different types of narrative that populate everyday talk, and they proposed a generic structure for gossip. They made the following observation:

Storytelling is very common in casual conversation. It provides conversationalists with a resource for assessing and confirming affiliations with others.

Like McCarthy, Eggins and Slade viewed interactional speech genres as crucial in establishing, negotiating, and maintaining group identity. Through stories that illustrate and dramatize cultural values, conversational participants manage in-group membership.

Ultimately, what distinguishes the systemic-functional genre analyst is his or her focus on the text (spoken or written) as the source of evidence for generic classifications. The procedure is an iterative one: The analyst gathers together examples of the genre, looks at their structure, and breaks each example down into purpose-driven stages. Because each stage has a different purpose, the assumption is that each stage will be differently realized linguistically. The analyst, therefore, seeks to describe the ‘realization patterns’ of each stage of the generic text. The presence of distinctive patterns reinforces or challenges the analyst’s intuition that the texts are generically related. Critics argue that the procedure is circular: If the analyst finds an example that does challenge his or her intuition, the model is simply adapted to accommodate the awkward text. Thus, the model is never ‘proven wrong.’ However, advocates of this type of genre analysis would counter that the circularity of the process is inevitable; describing the potential structure of a genre entails an ongoing series of refinements, because the nature of a genre changes as society’s demands evolve (e.g., Halliday and Martin, 1993). The way that society

shapes genres is the focus of the approach taken by North American school of analysts known as the 'New Rhetoricians.'

Genre in 'the New Rhetoric'

The evolving nature of genres is a preoccupation for at least some of the American genre analysts known as the 'New Rhetoricians' (cf., Freedman and Medway, 1994). The focus of the New Rhetoric is "centered not on the substance or the form of discourse but on the action it is used to accomplish" (Miller, 1984: 151). This school of genre analysts, therefore, situates genres in a thick ethnographic description of the communities that give rise to them, whether these communities are tax accounting firms (Devitt, 1991), bank offices (Smart, 1993), or scientific researchers (Bazerman, 1988; Myers, 1990).

For example, Bazerman (1988) looked at the gradual evolution of the experimental article in science and accounted for its changing form and structure in the evolving character and activities of the academic communities that have increasingly come to communicate through research papers. Thus, the experimental article grew out of the broadening of the scientific community in the age of Newton and of the substitution of the replicable experiment for the public demonstration. As experiments became more sophisticated and costly, replicability in principle replaced replication in practice; meanwhile, the success of the physical sciences gave their preferred forms of communication a prestige that was borrowed by other disciplines such as psychology and the social sciences. In those disciplines that are less obviously amenable to empirical research, the formal elements of the research article have a persuasive as much as a practical function. The moral of the New Rhetoricians' work on genre is that it is a negotiable 'social fact,' rather than an invariable set of conventions, as for example, in Bazerman (1988: 8):

Formal definitions, expected features, institutional force, impact, and understandings of the genre vary through time, place, and situation. That variation is an important part of the story. Each new text produced within a genre reinforces or remolds some aspect of the genre; each reading of a text reshapes the social understanding. The genre does not exist apart from its history, and that history continues with each new text invoking the genre.

Although New Rhetoricians are concerned that students understand the history and changing nature of genres, they are less inclined to offer formulaic descriptors of specific generic texts. In this, they differ both from the systemic functionalists and from those who come to genre analysis from applied linguistics, and specifically English for Specific Purposes (ESP).

Genre in Applied Linguistics

Applied linguists' analyses of genre share something of the approaches of both the systemic-functionalist school and the New Rhetoricians. Like the latter, they favor ethnographic descriptions of the 'discourse communities' who use genres to achieve social actions (cf., the notion of a 'rhetorical community' proposed by Miller, 1994). It is the needs of the discourse communities that are linked to the formal qualities of generic texts, usually described as a sequence of 'moves' that recall the generic structure potential of the systemic functionalists.

One of the best-known accounts of genre in this tradition is Swales' (1981, 1990) account of research article introductions in the sciences and social sciences. He refined his model into a three-move sequence, the overall function of which within the academic community is to 'create a research space.' This goal is accomplished by 'establishing a territory' (for example, by making a topic generalization and surveying the literature); 'establishing a niche' (for example, by questioning past research or adding to its scope); and 'occupying the niche' (for example, by previewing one's own research). Within the research community, the research article introduction is used rhetorically to align oneself with or against a research tradition and to frame stronger and weaker claims to knowledge. Further work along these lines has been published on business correspondence (Bhatia, 1993), quantity surveying reports (Marshall, 1987), and economics discourse (Dudley-Evans and Henderson, 1990).

Where systemic functionalists rely initially on the genre analyst's intuitions to break down a text into purposive stages, focusing mainly on multiple examples of the text type and looking for realizational patterns that justify the intuitive categorizations, the applied linguist checks his or her stages or moves against evidence garnered from the discourse community, through observation and interview.

Changing Conceptions of the Discourse Community

The 'discourse community' concept was based on the sociolinguistic notion of the speech community, whereby similarities in speech could be accounted for by the speakers' living in a community defined by geographical space, social class, gender, ethnicity, and so on. In a discourse community, the members may be dispersed widely and of different social classes, genders, and ethnicities, but they are linked by a common set of communicative purposes; for example, they might need to write research articles

for international refereed journals, or they might need to write business letters, such as letters of application for a job. For Swales (1990), discourse communities have six identifying characteristics:

1. A discourse community has a broadly agreed set of common public goals.
2. A discourse community has mechanisms of intercommunication among its members.
3. A discourse community uses its participatory mechanisms primarily to provide information and feedback.
4. A discourse community uses and hence possesses one or more genres in the communicative furtherance of its aims.
5. In addition to owning genres, a discourse community has acquired some specific lexis.
6. A discourse community has a threshold level of members with a suitable degree of relevant content and discursual expertise.

The influence on Swales' work of academic genres is clearly discernible here. A group of physicists or biologists, say, would have a set of research goals, journals, and conferences with which to give information and feedback. The group would have several genres at its disposal (research articles, reports to funding agencies, conference papers, popularizations), and its members would have relevant expertise (they would all likely be educated to degree level and beyond). However, more recent work has addressed the restrictive and static nature of this tentative description of the discourse community. It is difficult to fit diffuse discourse communities into Swales's model: What is the discourse community that produces and reads, say, a tabloid newspaper, or even a popular science article in a magazine like *New Scientist*? In those examples, writers and readers seem to have different levels of expertise. Junk mail seems to be a genre, but it is difficult to characterize the discourse community that produces or consumes it. Several attempts have been made to redefine the discourse community. Consider Barton's (1994: 57) definition:

A discourse community is a group of people who have texts and practices in common, whether it is a group of academics or the readers of teenage magazines. In fact, discourse community can refer to several overlapping groups of people: It can refer to the people a text is aimed at; it can be the people who read a text; or it can refer to the people who participate in a set of discourse practices both by reading and writing.

In this definition, Barton brought out the different orientations each individual has to the discourse community to which he or she belongs. We can imagine

a novice language teacher joining a teachers association and attending conferences and receiving its newsletter. After a while she might lose interest, stop attending conferences, and throw out the newsletter when it comes through her letterbox. Later, however, she might begin to undertake a further educational qualification. She might start attending conferences again, read the newsletter, and even contribute some articles based on her further study. She might then be invited to serve on a committee of the association and contribute to the making of policy and the organization of association events. In short, over time, the individual's status in the community shifts – it may be marginal or it may be central. A central member will have more say over the ethos of the community and will have more resources at his or her disposal for communication than a marginal member. If we suppose that this fictional teacher is typical of members of a discourse community, then we can begin to rethink discourse communities as large, fuzzy, porous, dynamic groupings, rather than as a static set of qualified individuals. Presumably, too, our imaginary teacher has other interests, domestic and public, that simultaneously involve her in different discourse communities to different degrees.

In addition, Barton pointed out that not all discourse communities have the participatory structure of, say, a teachers association. Magazines geared to teenagers will have a less participatory structure than newsletters produced by teachers' associations. Few of the readers will ever become writers for the magazine, and the readership will by its nature be transient and renewed, as people get older and move on. Even so, publications like this usually have a participatory mechanism, such as a letters page, where at least some of the readers can articulate their opinions or share their problems and thus constitute a visible community of which the reader is invited to feel part.

Bex (1996) adopted and adapted another concept from sociolinguistics in his redefinition of discourse communities: that of loosely knit and closely knit social networks (cf., Milroy, 1987). In her work on dialect preservation and change, Milroy observed that, when members of a speech community interact with each other regularly in their public and private lives (i.e., if they work and socialize together), then the community can be characterized as 'close-knit' and dialect is maintained. When people commute to work, interact with different people when they socialize, and have a number of links with 'outsiders,' then they are loosely tied to their speech community, and so dialect tends not to be preserved. Bex argued that this process has a parallel in discourse communities. The teacher who is an active member of an

association, both reading and writing articles for the association newsletter and regularly attending conferences and leading workshops, will be closely tied to this discourse community and will have internalized more fully its generic codes and conventions than a loosely tied teacher who sometimes reads the newsletter. Readers of a magazine for teenagers would generally not move much beyond a loose affiliation with a fairly disparate community. The nature of the discourse community and the nature of the individual's involvement with it, then, are both variable. Bex (1996: 66–67) emphasized the dynamic nature of discourse communities:

What I am proposing then is a complex interrelationship between social discourses, discourse communities, text production, and text reception. The model I have in mind is entirely dynamic. Individuals either produce, or produce interpretations of, texts according to the norms of the discourse community and the functions which the text is intended to serve within that discourse community. These are then verified by the group as meaningful, or challenged and refined. Such groups may develop highly characteristic modes of expression that remain internal to the group. However, these modes of expression are always situated historically, in that they develop from earlier 'ways of saying,' and socially, in that they interact with and take on (some) of the meanings of the larger social groups of which they are part.

Bex used this dynamic model of the discourse community to account for the generic conventions of a variety of texts, from academic texts to advertising to junk mail to literature. Such a dynamic model of the discourse community allows genre analysts to move away from the notion of genre as being confined to ritualistic sequences of speech or writing uttered to perform predictable actions by a specific group of qualified people.

More recent work on genre in applied linguistics continues to address the concept of the discourse community in academia and highlights the danger of thinking of even close-knit discourse communities, such as those of academic disciplines, as being homogeneous, harmonious groupings of individuals. Hyland (2000: 11) observed the following:

Communities are frequently pluralities of practices and beliefs which accommodate disagreement and allow subgroups and individuals to innovate within the margins of its practices in ways that do not weaken its ability to engage in common actions. Seeing disciplines as cultures helps to account for what and how issues can be discussed and for the understandings which are the basis for cooperative action and knowledge-creation.

Given the social nature of academic discourse, it is possible to look at some of its features in terms of

how the social relations within the academic communities are negotiated. Myers (1989), for example, showed how pragmatic conventions of politeness are negotiated, even within scientific writing.

Summary

As the above discussion shows, conceptions of genre – literary and nonliterary – vary according to the interests of the analysts. Literary theorists are concerned with the categorization of literary texts and how their conventions are elegantly maintained or wittily subverted. Linguists are concerned with the relation of texts to context and focus in particular on the predictability or unpredictability of elements of the text. As a result, some analysts have focused on the descriptions of highly predictable, ritual, transactional texts, many of which seem banal in nature, such as recipes (Eggins, 1994) or reprint requests (Swales, 1990). More recently, there has been a greater attempt to identify generic patterns in less predictable interactional texts, such as casual conversation (Coupland, 2000; Eggins and Slade, 1997). In the systemic- functionalist tradition (e.g., Halliday and Hasan, 1989), the analyst collects comparable texts and attempts to find in them predictable, goal-oriented elements that are characterized by similar realizational patterns. The New Rhetoricians collect comparable texts and set them in a rich ethnographic context that attempts to account for the engagement of the individual text with the dynamic history of the genre to which it belongs. The applied linguists, whose concern is less to explain and more to teach generic conventions to novices, take from both of the other approaches and identify predictable 'moves' in generic texts while explaining their function with reference to the communicative purposes of the discourse community.

The concept of the community and its communicative needs has been central to recent conceptions of genre in linguistics. Even here, the notion of the discourse community has rapidly evolved from that of a static group of experts with clearly defined goals. The discourse community is now perceived as a diffuse group of individuals with different levels of expertise and changing social relations, whose communicative needs more or less coincide at different points of time. The logical extension of this line of thought is to consider how individuals understand genres. Chilton and Schäffner (2002: 20) wrote

Participants in a linguistic interaction conceive of the interaction as being of a certain kind, as proceeding according to certain patterns of linguistic interaction that they have conceptualized in memory, and in which they may be more or less skilled. The conceptualization and its deployment in the ongoing activity define that

activity: There is no genre form independent of the participants' conceptions and preconceptions.

There is truth in this assertion, or systemic functionalists, New Rhetoricians, and applied linguists could not begin to group together those texts that they believe belong to the same genre and begin their analysis. However, genre analysis can be conducted with reference to the individual's knowledge and expectations, the structure of the discourse communities in which he or she is situated, and the more-or-less conventional texts produced to serve those communities' communicative purposes.

Genres in Political Discourse

N Fairclough, Lancaster University, Lancaster, UK

© 2006 Elsevier Ltd. All rights reserved.

A 'genre' is a more or less stabilized and habitual linguistic way of acting and interacting, characterized by a distinctive linguistic form or structure, associated with specific communicative purposes, and with particular social or institutional contexts (Swales, 1990; Bhatia, 1993). For instance, giving a speech, conducting an interview, and having a debate are all types of political genre. The category of 'genre' is related to what some scholars call 'text type' (de Beaugrande and Dressler, 1981), and to 'activity type' (Levinson, 1979). Analysis of the linguistic forms of genres sometimes focuses on 'generic structures' (Halliday and Hasan, 1989), the overall organizational pattern that distinguishes one genre from another, seen in terms of particular elements (or 'stages') occurring in a particular order – for instance, news reports in the press characteristically consist of a headline, plus a lead paragraph that summarizes the story, plus a variable number of 'satellite' paragraphs that fill out details. Bell and van Leeuwen (1994: 124–177) analyze "adversarial political interviews" in this way. Other more cognitively oriented research analyzes the characteristic topical structures of genres in terms of macrostructures and macrotopics (van Dijk, 1980). Genres also have distinctive features of linguistic form at other levels of analysis. For instance, the organization of 'turn-taking' (the distribution of turns at talking between participants) in political interviews is different from that in doctor-patient consultations (Heritage and Greatbatch, 1991). And there are genre differences in intertextuality – the way one text is connected with others – for example, scientific articles and political reports in newspapers represent the words of others in different ways (de Beaugrande and Dressler, 1981).

Pragmatic research on genre focuses on the importance of contextual cues in the way people interpret texts. One approach is in terms of prototype theory (Rosch, 1973), which helps to explain why texts that differ in their linguistic structure from central instances of a particular genre may nevertheless be interpreted as instances of that genre on the basis of contextual cues – for instance, an article written by a scientist on the basis of scientific research in a scientific journal is likely to be interpreted as a scientific report, even if it differs linguistically quite markedly from most scientific reports (Paltridge, 1995).

Genre can be seen as one of three main analytical categories in discourse analysis: a genre is a way of

(inter)acting, a 'discourse' is a way of representing particular aspects of the world (e.g., there are liberal, conservative, and social democratic discourses in the field of politics, which represent matters such as social welfare differently), and a 'style' is a way of being, an identity (e.g., there are different leadership styles in politics, such as the styles of British Prime Ministers Winston Churchill, Margaret Thatcher, and Tony Blair). Genres are best distinguished at the level of social practices that are relatively stable and durable over time, and particular concrete events, such as an actual political speech or interview, can be analyzed in terms of which genres and combinations of genres they draw upon. Much actual political text and talk is hybrid with respect to genres, i.e., combines different genres together (Fairclough, 1995a,b; Lauerbach, 2004).

An account of specifically political genres faces the difficulty that the field of politics is not unambiguously delimited but is socially constructed, and open to different competing constructions. The feminist slogan of the 1960s and 1970s, 'the personal is political,' is one indication of the difficulties here. Are we to assume a clear separation between the personal and domestic as elements of 'private' life, on the one hand, and politics as an element of 'public' life, on the other? Are gender relations in the household a form of political relation, or do political relations only obtain between the parties and factions of parliamentary politics? What about extraparliamentary movements and campaigns, such as those of environmental groups or protests against the policies of the World Trade Organization – are they a part of politics? Is there a clear distinction between politics and government, or politics and media, given that government is so much the target and focus of politics, and that so much of even parliamentary politics is now mediated through the press, television, and even the Internet? And are we to regard talk of the politics of organizations (such as businesses and universities) as merely a metaphorical appropriation of the term, or see the field of politics as including the many different types of organization as well as 'national' politics? What about local politics, international politics, and what is increasingly referred to as 'global' politics? How one defines and delimits politics is itself a political choice, and it determines how one delimits the genres of politics.

Here is a relatively broad view of politics, one that focuses on the political sphere as a distinct and partially institutionalized area of social life, and therefore excludes household politics and the politics of particular organizations, such as schools or workplaces.

The political sphere, for purposes of this article, is that dimension of social life in which different social groups act in pursuance of their particular interests, needs, aspirations, and values. Political interaction between different social groups has both a cooperative character in that there is a search for a *modus vivendi* and a conflictual character in that there is a struggle for power (Chilton and Schäffner, 2002). They may do so at different scales (locally, regionally, nationally, and internationally), although it is the national scale that has received most attention in political theory and analysis, problematically, given the current growth of international political entities. Politics in this sense includes the political system (parliament, political parties, elections, structures of political communication, etc.), but also includes 'grassroots' or 'social movement' politics, and the 'mediatized politics' of the printed and broadcast media (Fairclough, 1995a). These are analytically distinguishable but overlap considerably in concrete events. The political sphere can be seen as the sphere that connects the state and the lifeworld (or 'civil society'), and one dimension of its internal heterogeneity is that it ranges from stabilized and institutionalized structures to unstable, fluctuating, emergent political tendencies and initiatives. Settled practices and vested interests precariously coexist with movements in and pressures from the lifeworld, and what counts as political (open to action in pursuance of alternative policies) shifts as areas of social life are politicized and depoliticized, brought into and taken out of the sphere of politics (Muntigl, 2002).

In accordance with this view of politics, political genres will be taken to include genres associated with the political system (e.g., parliamentary debate, political manifestos and programs, parliamentary or party conference speeches by political leaders, policy documents), mediatized political genres (e.g., political news reports, political interviews, political 'chat shows,' party political broadcasts, political advertising in the press and on billboards), the political public sphere (e.g., public meetings, campaign literature of social movements, political forums, and focus groups). The range of genres is thus extensive, and this list of examples is by no means exhaustive. Most of the literature has tended to focus on particular genres (political interviews and parliamentary debates have, for instance, received considerable attention), but there are arguments for also attending, particularly in the case of more institutionalized areas of politics, to 'chains' or 'networks' of genres that constitute the discourse dimension of political systems, the discourse 'technologies' so to speak of institutionalized politics. Thus, in the area of political communication there are systematic connections

between, for instance, policy documents or major political speeches, press releases and news conferences, and reports in the media, and there are regular and predictable transformations in language as material is moved along such a chain of genres (Fairclough, 2003).

This article focuses on linguistic research on political genres (including linguistic, pragmatic, sociolinguistic, discourse, and conversation analysis), but it is important to acknowledge that various disciplines contribute to analysis of political genres, including political science and media studies. Very limited reference is made here to this broader body of research (Dryzek, 1990; Corner, 1995; Livingstone and Lunt, 1994), but research on political discourse in general and political genres in particular is most productively conceived as interdisciplinary analysis in which language and discourse analysts can make a specific contribution to political, cultural, and media research, while at the same time enriching themselves theoretically and methodologically through dialogue with other disciplines (Fairclough, 2000).

This article focuses on four genres associated with the political system, mediatized politics, and the political public sphere: political interviews, political speeches, policy documents, and public sphere dialogues.

Political Interviews

Political interviews have attracted considerable research interest as the genre that has been most potent in the way television has transformed the character of politics in the past 50 years. The history of broadcast interviews (Bell and van Leeuwen, 1994) shows a shift from deferential journalists putting tentative questions to distant and sometimes impatient politicians, to a situation in which journalists confidently and sometimes aggressively quiz or try to corner politicians (on behalf of the public as they commonly claim), while politicians have become accomplished television performers and even media personalities. The boundary between politics and media has radically shifted, and politics now has a thoroughly mediatized character.

One body of research on political interviews has adopted the method of 'conversation analysis' (Heritage and Greatbach, 1991; Clayman and Heritage, 2002). Conversation analysis focused initially on everyday conversation but increasingly has turned its attention to institutional talk in, for instance, doctor-patient interactions and news interviews, treating these as adaptations of everyday conversation to fit specific institutional purposes that reduce the diversity of features characteristic of

the latter, and develop the normal conversational activities that are retained in specialized ways. For instance, features of 'turn-taking' (organizing the distribution and alternation of participants' turns at talking), which are a pervasive characteristic of conversation, are retained but in a distinctive form. Types of turn are distributed according to the institutional role of participants, most obviously in that it is only interviewers (IR) that ask questions, and interviewees (IE) that provide answers. IR questions are commonly preceded by statements that are standardly treated by IE as 'prefaces' to questions in that they do not respond to such statements but wait for a question before responding. There are features of the design of news interview talk which (a) achieve the 'task' that participants have to produce talk for an 'over-hearing' news audience, talk that is addressed to an audience rather than addressed by IR and IE to each other (which would position the audience as 'eavesdroppers' on a conversation), and (b) meet the constraint that interviewers should "maintain a stance of formal neutrality towards interviewee statements and positions" (Heritage and Greatbatch, 1991: 106). For instance, 'response tokens' (such as 'yes,' 'oh,' 'really,' 'mm hm'), which are regularly produced in everyday conversation by co-participants in the course of an extended turn by one participant, are not produced by IR in the course of extended answers by IE, and, in withholding them, IR 'declines' the role of primary addressee in favor of the news audience. And IR questions that might be taken to be 'hostile' and therefore in breach of IR neutrality are generally not treated as expressing IR's opinion but are merely designed to solicit IE's viewpoint. Participants in news interviews overwhelmingly comply with such interactional norms.

Although conversation analysts emphasize that the norms of political interview are socially constructed and subject to social change, they have tended to understate the diversity and variability of contemporary forms of political interview. I see this as a problem of levels, as I indicated earlier. Conversation analysts have described a genre of political interview that has been perhaps the dominant genre, one with a normative power in terms of what interviewers and interviewees tend to recognize as what they should do, one that has achieved a certain stability and durability at the level of the social practices of politics, which can constitute a powerful point of reference in actual political interviews but is not instantiated in any simple way within them. Actual events, actual text, and talk are more diverse and hybrid with respect to genres. One response to this is to distinguish different types and styles of political interview (Bell and van Leeuwen, 1994), but clear-cut typologies are

difficult to arrive at. Another approach is to recognize that although there is a measure of stabilization of types and styles (including the personal styles of leading broadcast journalists), political interviews as events are performances that variably, and more or less innovatively, draw upon and combine genres which have a certain stability and uniformity at the level of social practices (Fairclough, 1995a,b; Lauerbach, 2004).

Bell and van Leeuwen (1994) analyze one particular type of political interview, the 'adversarial' political interview, in terms of its generic structure, seeing it as made up of the following 'stages': (a) greeting, (b) soliciting opinion, (c) checking, (d) challenging, (e) entrapment, and (f) release. The interview begins on a cooperative note, with the interviewer as host greeting the interviewee as guest. The interviewer then asks an 'open' question giving the interviewee the chance to state his views in the way that he wants to ('soliciting opinion'). The shift from cooperation to contest begins with 'checking,' in which the interviewer prepares the ground for challenges by checking facts and figures. The interviewer then moves onto the offensive by confronting the interviewee with statements that contradict or weaken the latter's position ('challenging'). 'Entrapment' is a sort of verbal checkmate, a statement with which an interviewee can neither agree nor disagree without damaging his or her position. The final stage is 'release,' a return to cooperation, in which the interviewer asks a question (often dealing with future prospects or aims) that the interviewee is allowed to answer without challenge. Some of these stages may be absent from adversarial interviews – the interviewer may move straight into challenges after the greeting – and the central stages occur recursively (e.g., there may be several sequences of challenge and entrapment). Although the whole of such an interview consists of a series of questions and answers, the interviewer's questions vary in their linguistic form and in their illocutionary force in different stages of the interview. Their analysis thus moves toward forms of pragmatic analysis, which are more fully developed in other research (e.g., Fetzer, 2002), in which the focus is on the relationship between what is said and what is meant, and on such specific issues as directness and indirectness, politeness and impoliteness, and presupposition.

Fairclough (1995b) is an analysis of a political panel interview in the course of an election campaign between a television journalist and representatives of the three main British political parties. The focus is on genre hybridity, on the slippage between conventional political interview of the type described by Heritage and Greatbatch (1991), everyday

conversation, and an entertainment genre that at points approximates a comedy routine. Such genre hybrids are a general characteristic of mass media and a specific characteristic of mediatized political genres. They are a facet of the fluid and shifting character of the political sphere, that is, of its shifting relations with other spheres, including those of the media and of everyday life (the 'lifeworld'). Another example is political 'chat shows,' in which politicians engage in 'chat,' – conversational language specialized for purposes of entertainment – rather as film stars or pop idols do (Livingstone and Lunt, 1994; Fairclough, 1995a).

Political Speeches

I referred at the beginning of this article to the common view of the 'generic structure' of genres – particular elements occurring in a particular order. I also defined a 'genre' as a more or less stabilized and habitual linguistic way of acting and interacting. These 'elements' are characteristically themselves actions – so that a genre is a way of (inter)acting, which is composed of constituent actions. However, the assumption that these constituent actions are necessarily strictly ordered is not sustainable. They are in highly ritualized genres (e.g., the official opening of a new parliamentary session), but this is not a defining feature of genres as such. For instance, Graham, Keenan, and Dowd (2004) analyze historical continuities in 'call to arms' speeches from Pope Urban II (1095) to George Bush (2001). They identify four 'generic features' of such speeches: (1) an appeal to a legitimate power source that is external to the orator, and which is presented as inherently good (e.g., God, or the nation), (2) an appeal to the historical importance of the culture in which the discourse is situated, (3) the construction of a thoroughly evil Other (e.g., terrorism), and (4) an appeal for unification behind the legitimating external power source. The authors analyzed some 120 of such speeches, and the particular realization, including the particular ordering of these generic elements, is predictably variable.

A different approach to analysis of political speeches is based on 'functional pragmatics,' which aims at reconstructing the 'deep' actional structure of texts through analysis of their textual 'surface.' Sauer (2002) analyzes one of a series of commemorative speeches (British Prime Minister John Major's speech) given by senior politicians on the 50th anniversary of the allied victory in World War II. One focus of his analysis is the 'importation' of textual elements into this primarily epideictic address (eulogy), which gives it a heterogeneous character, including a mixture of genres. Specifically, these are

elements of Conservative Party neoliberal ideology that introduce the genre of party political speech. Sauer (p. 131) also notes a 'populist' element that enters through "the classical rhetorical technique of contrasting sublimity with popular expressions" (e.g., "We are, as it were, still rubbing our eyes after 1989 wondering if it can be real"), a characteristic I also identified in Tony Blair's speech on the occasion of Princess Diana's death (Fairclough, 2000). Such 'conversationalization' of political language is pervasive in contemporary politics.

Muntigl (2002) focuses on the innovative political work that is done in major political speeches, specifically the 'politicization' of certain issues in the sense of constituting them as issues for political debate, and the 'depoliticization' of others. He analyzes a speech by the European Commissioner responsible for employment, industrial relations, and social affairs, Commissioner Flynn, in which employment policy at a European Union (EU) level is opened up as a political issue (politicized), but, at the same time, is depoliticized by projecting the particular policies adopted by the EU as the only possible ones, ruling out alternatives. Muntigl's analysis includes the generic structure of the speech, and semantic and grammatical analysis of how particular social groups and their policy positions are positioned in relation to each other. I adopted a similar approach to a major policy speech of Tony Blair on the "new international community" at the time of the Kosovo war (Fairclough, 2000), showing how the speech constituted 'the international community' as a new and only apparently inclusive actor in international affairs and especially military interventions in the affairs of sovereign states, which could be interpreted in Muntigl's terms as the simultaneous politicization of interventions on claimed 'humanitarian' grounds and their depoliticization through excluding alternatives to the particular policies proposed. In both cases, one can see an important element of the action of such policy speeches in terms of space: 'carving' out a new EU space for employment policy interventions, and a new 'global' space for military interventions on the part of a largely self-appointed 'international community' (in effect, the United States and its allies). In discourse analytical terms, this political genre contributes to the emergence and hegemony of new discourses.

Policy Documents

Discussed here briefly is work on the genesis of policy documents within the EU (Wodak, 2000), which draws attention to a complex collective and negotiated process of production associated with this genre (as also with other political genres, such as political news reports). Successive drafts of the

policy document were debated and altered in the EU Competitiveness Advisory group, which consists of representatives of the employers and the trade unions, as well as some politicians and bureaucrats. This analysis locates this one genre as an element in a chain or network of genres (including committee meetings, expert opinions, documents of the EU Commission) and points to relations of recontextualization between such genres, and to the characteristic transformations that take place as elements are moved from one genre (e.g., committee discussion) to another (e.g., the policy document). One aspect of these relations of recontextualization is their ‘filtering’ effect: things that can be said in a meeting cannot be directly recontextualized in a policy document.

Public Sphere Dialogues

My fourth example illustrates most clearly the potential of interdisciplinary research on political genres. The foundational work of the social theorists Jürgen Habermas and Hannah Arendt on the public sphere has made it clear that the question of the public sphere is centrally the question of what forms of dialogue are available for public deliberation. Their work has been developed by Dryzek’s studies of ‘deliberative democracy’; the final chapter of Dryzek (2000) can be interpreted as a normative discussion of the genre of public sphere deliberation or dialogue. None of these theorists is a linguist, so what they say about public sphere dialogue is merely schematic from a linguistic point of view. However, their work can be ‘operationalized’ in the analysis of actual dialogues in a way that fruitfully combines social theory and analysis of discourse and genre.

The ‘critical’ analysis of discourse has often focused on negative critique – a critique of the dominant forms (including genres) of discourse. However, part of the objective of critical analysis is also ‘positive’ critique – the normative specification of alternatives, not in a purely hypothetical way, but on the basis of forms that actually exist, if often in a marginalized way. In the case of public sphere dialogue, one can specify normative generic conditions on the basis of (to give the familiar term an ironic twist) ‘best practice,’ and evaluate actual dialogues in terms of these normative conditions (Fairclough, 1999). On the basis of the theoretical work on the public sphere discussed earlier, the following characteristics of good public sphere dialogue can be specified:

- Regulation: maximally open to diverse discourses and voices, interaction jointly managed by all participants

- Emergence: new individual, collective (as members of groups) and universal (as citizens, and human beings) identities can emerge
- Action: as Arendt (1998: 200) puts it, “power is actualised where word and deed have not parted company” – good public sphere dialogue leads to action, has effects on the world

Although these characteristics are formulated in an abstract way, their presence or absence in dialogue can be measured in more precise analytical terms – for instance, with respect to the first characteristic, the form of management of interaction can be specified in terms of features of turn-taking. The third characteristic points to the question of how public sphere dialogue is positioned in genre chains or networks, and it indicates that particular institutionalized regimes of governance have a partly discourse character – specifically, in this case, the existence (or nonexistence) of systematic procedures for feeding public dialogue and deliberation into policy-making processes can be seen as partly a matter of the existence of established relations of recontextualization between the genre of public sphere dialogue and the genres of policy making.

Conclusion

A vast amount has been written on political genres, including traditional and more modern forms of rhetorical analysis of especially political speeches. This article has drawn selectively from more recent research. I highlight two characteristics of political genres that have been relatively neglected but are crucial if genre and discourse analysts are to make an effective contribution to political research.

The first is the fluid and shifting character of political genres, their hybrid character, and their openness to new forms of hybridity. Politics is in a sense a ‘space between,’ a social sphere that, on the one hand merges into the structures of the state and the market, and, on the other, connects with the more open and diverse sphere of the ‘lifeworld,’ everyday life. Relations between politics and business, media, leisure, and so forth fluctuate as part of processes of social change. For instance, there is a common view that the ‘official’ politics of the political system has become moribund as states have begun to function more as facilitators for the emergent ‘global’ form of ‘hypercapitalism’ – real policy options have ceased to exist, old differences in political ideologies have become meaningless – and one can see the increasingly mediatized character of politics, its increasing focus on leaders who are effective television personalities, its preoccupation with image at the expense of political ‘message,’ as discourse facets of what are arguably structural changes.

The second is the interconnection of political genres, the relations that are contracted between them in genre chains or networks, the relations of recontextualization that obtain between them, and the linguistic transformations entailed when, for example, material from committee meetings is recontextualized in policy documents. This focus accords with the partly institutionalized character of politics as political system, including pressures to incorporate the public sphere (e.g., the contemporary integration of 'focus groups' into the political apparatus) and 'life-world' politics (e.g., various originally activist NGOs, which have become institutionalized). The political sphere is germane to the constitution of 'regimes of governance' on different scales ('global,' macro-regional, e.g., the EU, national, and local), which regulate (with varying degrees of success) social interactions, relations, and identities. And such regimes of government have a partly discourse character, which is best captured by seeing them as distinctive networks of genres. Especially in the context of increasing 'globalization,' in which such regulation operates with extreme rapidity across vast distances of social space and across scales, networks of political genres are an inherent part of regimes of government.

Gesture and Communication

D McNeill, University of Chicago, Chicago, IL, USA

© 2006 Elsevier Ltd. All rights reserved.

As a field of study, gesture has become energized in recent years. There is now an organization (International Society for Gesture Studies) and a journal (*GESTURE*, founding editors Adam Kendon and Cornelia Müller). In preparing this article, I have aimed to balance the empirical basics of gestures with a theoretical perspective from which to regard gestures and see what insights they bring to an understanding of the nature of language.

The word ‘gesture’ covers a multiplicity of communicative movements, primarily but not always of the hands and arms. Often, gestures are assumed to comprise a channel distinct from speech, but careful investigation challenges this traditional view. Gestures and language are best thought of as a single system, larger than either language or gesture as traditionally assumed. It will be useful to begin our survey by drawing distinctions among different actions, all of which might be termed ‘gesture.’

Kendon's Continuum

Adam Kendon once distinguished gestures of different kinds along a continuum that I named ‘Kendon's Continuum,’ in his honor (McNeill, 1992). The gestures we are mostly concerned with are the ‘gesticulations.’ See McNeill (1992) for details.

‘Gesticulation’ is motion that embodies a meaning relatable to the accompanying speech. Gesticulation is by far the most frequent type of gesture in daily use and it covers many variants and usages. It is made chiefly with the arms and hands but is not restricted to these body parts – the head can take over as a kind of third hand if the anatomical hands are immobilized or otherwise engaged, and the legs and feet too can move in a gesture mode. In a large sample of gestures, Shuichi Nobe (2002) found that the stroke phase of the gesticulation is synchronous with the coexpressive speech about 90% of the time (gesture phases are defined below). When strokes are asynchronous, they slightly precede the speech to which they link semantically, usually because of brief hesitations, and the time gap is small. Gesticulations rarely if ever follow their coexpressive speech (Kendon, 1972). There is no basis for the assertion that strokes occur during hesitations. Such a view has attained urban legend status, but it is based on a misrepresentation of the original study by Brian Butterworth and Geoffrey Beattie (Butterworth and Beattie, 1978).

They reported that the rate of gesture occurrence was higher during speech pauses than phonations. However, far more gestures occur during phonation than pauses, so the 90% figure is the result (Nobe also did not replicate their higher gesture rate during pauses, possibly because of different communicative situations: Nobe was looking at narrations, while Butterworth and Beattie had analyzed college tutorials, where gestures during pauses are likely to have had ‘turn suppression’ functions not prominent in narrations). The expression ‘coexpressive speech and gesture’ is explained below. Other controversies have revolved around the issue of whether gesticulations are communicative – ‘made for the listener’ – or beneficial primarily for speech production – ‘made for the speaker’ (cf. Krauss *et al.*, 2000; Alibali *et al.*, 2000). Gesticulations combine both universal and language-specific features. Speakers of every language studied thus far (and this is a sizable list: in our lab alone, English, Japanese, Mandarin [Mandarin Chinese], Korean, Spanish, French, German [Standard German], Italian, Turkish, Georgian, Russian, American Sign Language, Taiwanese Sign Language, and a few African languages) produce them, and the gesticulations for the same events in a cartoon stimulus show clear similarities across these languages. Yet there are also striking differences which are traceable to characteristics of the languages the gestures are cooccurring with, in particular whether the language is, in Leonard Talmy's typology (Talmy, 2000), S-type or V-type (see McNeill and Duncan, 2000). Gesture space is oriented in terms of absolute compass direction by speakers of Guugu Yimithirr (Guguyimidjir) (an Aboriginal language with obligatory absolute orientation in its verb morphology) and also by speakers of Tzotzil (a Mayan language that lacks the lexical precision of directional reference as seen in Guugu Yimithirr [Guguyimidjir], but whose mode of living promotes exact spatial orientation, which is then embodied in gestures; see Haviland, 2000).

‘Speech-framed gestures’ are part of the sentence itself. The term is from Karl-Erik McCullough. Such gestures occupy a slot in a sentence, e.g., ‘Sylvester went [gesture of an object flying out laterally],’ where the gesture completes the sentence structure. These gestures time differently from gesticulations – they occupy a gap that fills a grammatical slot, rather than synchronizing with speech that is coexpressive.

‘Emblems’ are conventionalized signs, such as thumbs up or the ring (first finger and thumb tips touching, other fingers extended) for ‘OK,’ and others less polite. Kendon prefers the term ‘quotable gesture,’ referring to a potential for a more or less

complete verbal translation – ‘OK’ translating into terms of approbation, for example. Emblems or quotable gestures are culturally specific, have standard forms and significances, and vary from place to place. Kendon (1995) has for some years studied the gesture culture of Naples, a locale with an exceptionally rich repertoire of quotable gestures (cf. de Jorio, an early 19th-century figure, in Kendon, 2000). These gestures are meaningful without speech, although they also occur with speech. They function like illocutionary force markers, rather than propositions, the mode of gesticulation, and the timing when they occur with speech, being quite different. A single Neapolitan emblem for ‘insistent query’ (the ‘purse’ or *mano a borsa*: prototypically, the hand palm up, the fingers and thumb loosely bunched together at the top, and rocking up and down) was observed in one case stretching over several utterances and then continuing into the next speaker’s turn, still demanding clarification. This gesture is not employed in North America (a similar-looking gesture is used to mean that something is ‘precisely so’), which illustrates the cross-cultural variation of the emblem. Emblems can blend both sequentially and simultaneously with gestures of other kinds. Many emblems have deep historical roots, far outlasting the spoken languages with which they occur. Some go back to Roman times (Morris *et al.*, 1979), including the infamous ‘finger,’ beloved of the American road – it would have been understood by Julius Caesar. Most emblems have iconic or metaphoric components. The contact of the thumb and forefinger in the ‘OK’ sign captures the idea of precision. But the emblem is also specified by a convention pairing the form of the gesture to the approbation meaning. The fixity of the emblem is the evidence of this. Putting the *second* finger in contact with the thumb is still precision but no longer is the ‘OK’ sign of approbation.

‘Pantomime’ is dumb-show, a gesture or sequence of gestures conveying a narrative line, with a story to tell, produced without speech. And at the other extreme of the continuum, ‘signs’ are lexical words in a sign language such as ASL. Sign languages have their own linguistic structures, including grammatical patterns, stores of words, morphological patterns, etc. The linguistic code of ASL is quite unlike that of English. Sign languages have evolved without the requirement of being coordinated with speech. In fact, hearing signers find producing speech and signs simultaneously to be disruptive to both. For an authoritative description, see Liddell (2003).

As one moves along Kendon’s continuum, two kinds of reciprocal changes occur. First, the degree to which speech is an obligatory accompaniment of gesture *decreases* from gesticulation to signs.

Second, the degree to which a gesture shows the properties of a language *increases*. Gesticulations are obligatorily accompanied by speech but have properties unlike language. Speech-framed gestures are also obligatorily performed with speech, but relate to speech in a different manner – sequentially rather than concurrently, and in a specific linguistic role. Signs are obligatorily *not* accompanied by speech and have the essential properties of a language. Clearly, therefore, gesticulations (but not the other points along Kendon’s continuum) combine properties – gesture with language – that are unlike, and this combination occupies one communicative instant. A combination of unalikes, at the same time, is a key psycholinguistic fact and a framework for an imagery–language dialectic. The remainder of this article focuses on gesticulations. If no ambiguity results, from here on I shall use the simpler term ‘gesture.’

Traditions of gesture study not summarized in this article because of length are gestures of the theater (Fischer-Lichte, 1992), histories of gesture studies (Bremmer and Roodenburg, 1991), ‘neurogestures’ (McNeill, 2005), gestures in human–computer interface design (Kita *et al.*, 1998), methods of gesture transcription and measurement (Quek *et al.*, 1999), and the gestures of children (Bates and Dick, 2002), including home signs (Goldin-Meadow, 2003).

The Iconic, Metaphoric, Deictic, Beat Quartet

These categories or, as I will later say, dimensions are inspired by the semiotic categories of C. S. Peirce. Elena Levy and I proposed a classification scheme with four categories: iconic, metaphoric, deictic, and beat. All are gesticulations or speech-framed gestures on Kendon’s continuum.

Iconic: Such gestures present images of concrete entities and/or actions. For example, appearing to grasp and bend back something while saying “and he bends it way back.” The gesture, as a referential symbol, functions via its formal and structural resemblance to event or objects.

Metaphoric: Gestures are not limited to depictions of concrete events. They can also picture abstract content, in effect imagining the non-imageable. In a metaphoric gesture, an abstract meaning is presented as if it had form and/or occupied space. For example, a speaker appears to be holding an object, as if presenting it, yet the meaning is not presenting a concrete object but an idea or memory or some other abstract ‘object’ (for examples, see McNeill, 1992; Cienki, 1998). This is a gestural version of the conduit metaphor that appears in expressions such as ‘he packed a lot into that lecture,’ where the lecture is presented as

a container and the message as its contents (Lakoff and Johnson, 1980). Recent work on metaphoric gestures has greatly expanded the subject. Müller (2004) developed a new theory of metaphor as a dynamic process (whereby 'sleeping' metaphors are 'awakened' in context) in which metaphoric gestures play an essential part. Parrill and Sweetser (forthcoming) develops a new theoretical account based on 'mental spaces blending theory.' Metaphoric gestures often indicate that the accompanying speech is meta rather than object level – for example, saying "the next scene of the cartoon" and making a conduit cup of meaning gesture (iconic gestures, in contrast, favor the object level).

Deictic: The prototypical deictic gesture is an extended index finger, but almost any extensible body part or held object can be used. Indeed, some cultures prescribe deixis with the lips (Enfield, 2001). Deixis entails locating entities and actions in space *vis-à-vis* a reference point, which Karl Bühler called the 'origo' (Bühler, 1982; Haviland, 2000). Much of the pointing we see in adult conversation and storytelling is not pointing at physically present objects or locations but is abstract pointing, which Bühler referred to as "deixis at phantasma." The emergence of abstract pointing is a milestone in children's development. In striking contrast to concrete pointing, which appears before the first birthday and is one of the initiating events of language acquisition, abstract pointing is not much in evidence before the age of 12 and is one of the concluding events (McNeill, 1992).

Beats: Such gestures are so called because the hand appears to be beating time. Other allusions to the musical analogy use the term 'baton' (Efron, 1941). As forms, beats are mere flicks of the hand(s) up and down or back and forth, zeroing in rhythmically on the prosodic peaks of speech. This rhythmicity has made beats seem purely speech related. However, they also have discourse functionality, signaling the temporal locus of something the speaker feels to be important with respect to the larger context. One can think of a beat as a gestural yellow highlighter.

With these four categories, Levy and I were able to classify nearly all gestures in the narrative materials we collected. Other researchers have proposed more finely subdivided categories.

Dimensions Rather than Kinds

I wish to claim, however, that none of these 'categories' is truly categorical. We should speak instead of *dimensions* and say: iconicity, metaphoricity, deixis, 'temporal highlighting' (for beats), social interactivity, or some other equally unmelodious (but accurate) terms conveying dimensionality.

The essential clue that these are dimensions and not categories is that we often find iconicity, metaphoricity, deixis, and other features mixing in the same gesture. Beats often combine with pointing, and many iconic gestures are also deictic. We cannot put them into a hierarchy without saying which categories are dominant, and in general this is impossible. A practical result of dimensionalizing is improvement in gesture coding, because it is no longer necessary to make forced decisions to fit each gesture occurrence into a single box.

Tight Binding

The temporal binding of speech and gesture is almost impervious to forces trying to interrupt it. The very heterogeneity of the following observations shows the inviolability of the speech-gesture unit (see McNeill, 2005 for details).

Gesture synchrony and DAF: Delayed auditory feedback or DAF has a dramatic effect on the flow of speech, which slows down, becomes hesitant and is subject to drawling and metatheses (spoonerisms). Nonetheless, despite the interruptions, speech and gesture remain in synchrony.

Gesture inoculates against stuttering: Mayberry and Jaques (2000) made two noteworthy observations. First, the onset of a gesture stroke inoculates against the onset of stuttering. Second, if stuttering begins *during* a stroke, the speaker's hand freezes in midair and may fall to rest. In both observations, we see an incompatibility between the interruption of speech in stuttering and the occurrence of the meaningful gestures.

Gestures of the blind: Congenitally blind speakers, who have never observed gestures, nonetheless do gesture and do so as frequently as sighted subjects, and gesture even when they know are talking to another blind person (Iverson and Goldin-Meadow, 1998). This is dramatic evidence of a speech – gesture bond.

Information exchange: Information received in a gesture may be recalled later as speech (not gesture) (Cassell *et al.*, 1999). Symmetrically, Kelly *et al.* (1999) observed subjects recalling information presented in speech as having been gestural.

Gestures and fluency: Speech and gesture become complex or simple in tandem, even to the point of jointly disappearing (the gesture disappears along with speech, rather than replacing it).

To sum up binding, speech and synchronous coexpressive gestures form a tightly bound unit, capable of resisting outside forces attempting to separate them, such as DAF, stuttering, lack of visual experience of gesture, and loss of fluency. Speech and gesture also spontaneously exchange information in memory,

so that when something is recalled the speaker cannot tell the original format. Tight binding clearly fosters an imagery–language dialectic by creating unbreakable psycholinguistic units within which it can take place.

Gesture Anatomy

The anatomy in question is temporal, an anatomy of ‘phases.’ The gesture illustrated in **Figure 1** includes all phases except a final, retraction phase, which did not occur in this case because a new gesture followed immediately. The speaker had been given a comic book to read and was retelling the story to a listener from memory. The transcription, by S. Duncan, is as follows: “so he gets a / hold of a big [oak tree / and he bends it way back].” Notation: / denotes a silent pause; [the onset of motion; underlining a hold; boldface the stroke;] the end of motion.

Unfolding in Time and Its Meaning

As this example illustrates, gestures pass through a series of phases, each with its own position and function in the gesture. The phases enable us to peer into performance dynamics. Kendon (1980) differentiated among what he termed “gesture units,” “gesture phrases,” and “gesture phases.”

A gesture unit is the interval between successive rests of the limbs. In the example, the gesture unit included not only the interval from ‘oak’ to ‘back,’ but also further speech and later gestures not shown.

A gesture phrase is what we intuitively call a ‘gesture’ and it in turn consists of up to five gesture phases, in sequence:

- Preparation (optional): The limb moves away from a rest position into the gesture space, where it can begin the stroke. The onset of preparation shows the moment at which the visuospatial content of the gesture starts to take form in the cognitive experience of the speaker. ‘Oak tree and’ coincided with the preparation phase in the illustration, and it is noteworthy that the preparation commenced with the first mention of the object in the preceding clause – as the idea was introduced, so the next image flicked on to become a gesture.
- Stroke (obligatory in the sense that, without a stroke, a gesture is not said to occur): The stroke is the gesture phase with meaning; it is also the phase with effort, in the dance notation sense of focused energy. In the example above, the stroke was the bending back, the hand in a grip around something thick, timed with the coexpressive ‘bends it way back.’

Figure 1 Gesture phases in the ‘and he bends it way back’ gesture. The insert is a frame counter (1 frame = 1/30 s.). The total elapsed time is about 1.5 s. Panel 1: Prepreparation position. Hand is shown just prior to lifting off from the armrest. Panel 2: A Prestroke hold occurs while saying ‘he’ – the hand waiting for ‘bends.’ This figure depicts the hand at the start position of the stroke (ready to pull down and to the rear). The preparation interval was slightly less than 1 s. Panel 3: Middle of stroke – ‘way.’ The hand has closed around the ‘oak tree’ and is moving downward and to the rear. Note how the speaker’s own position in space defines the location of the oak tree and the direction of the bending-back movement – the gesture framed according to a ‘first-person’ or ‘character’ viewpoint. Panel 4: End of stroke and beginning of the poststroke hold in the middle of ‘back.’ Hand is at its farthest point to the rear. After the poststroke hold, the hand immediately launched into a new gesture.

- Retraction (optional): The hands return to rest (not always the same position as at the start). There may not be a retraction phase if the speaker immediately moves into a new stroke, as was the case in the illustration.

In addition, Sotaro Kita (pers. comm.) identified:

- Pre- and poststroke hold phases (optional): Temporary cessations of motion either before or after the stroke motion; in the example a prestroke hold occurred during 'he' and a poststroke hold during the second half of 'back'; holds ensure that the meaningful part of the gesture – the stroke – remains semantically active during the coexpressive speech. Holds suggest that the stroke and the coexpressive speech comprises an idea unit created in advance, from the start of the preparation phase.

The gesture phases are organized around the stroke. This is the 'object' being presented. It is prepared for, withheld if need be until the coexpressive speech is ready, and held again until all linked speech is over. The full span of phases, from the beginning of preparation to the end of retraction, describes the lifetime of a particular gesture and its linked idea unit.

Coexpressiveness and Synchrony

Gesticulations (but not other points along Kendon's continuum) have the property that strokes synchronize with coexpressive speech. This section explains this concept. An example is illustrated in **Figure 2**. The speaker was describing a cartoon episode in which one character tries to reach another

Figure 2 Synchronous, coexpressive gesture with 'up through.' Accent indicates a stressed vowel.

character by climbing up a drainpipe on the inside. The speaker is saying "and he tries going **up through** it this time," with the gesture occurring during the boldfaced portion (the illustration captures the moment at which the speaker is saying the vowel of 'through'). Coexpressively with 'up' her hand rose upward, and coexpressively with 'through' her fingers spread outward to create an interior space. The upward movement and opening of the hand took place simultaneously, and both were synchronized with 'up through,' the linguistic package that carries the same meanings. The effect is a uniquely gestural way of packaging meaning – something like 'rising hollowness,' which does not exist as a semantic package of English at all. The gesture and the linguistic construction synchronize as a whole, not component by component. Thus, speech and gesture synchronize at the point where they are coexpressive and this, not the components, is the unit that aligns them.

Growth Points and Context

Synchronous combinations of such unlike modes of cognition – visuospatial-actional gesture synchronized with analytic-combinatoric speech – may be operative psycholinguistic units, termed 'growth points' or GPs (McNeill and Duncan, 2000). One way to think of a GP is as imagery that is categorized linguistically, an image with a foot in the door of language. A GP is inferred from the totality of communicative events, with special focus on speech-gesture synchrony and coexpressivity. It is called a growth point because it is meant to be the initial form of a thinking-for-speaking unit out of which a dynamic process of utterance and thought organization emerges.

The Psychological Predicate Regarding the GP as a psychological predicate (a term from Vygotsky, 1986 – not always a grammatical predicate) suggests a mechanism of GP formation in which differentiation of a focus from a background plays an essential part.

The concept of a psychological predicate illuminates the theoretical link between the GP and the context of speaking. Defining a psychological predicate requires reference to the context; this is because the psychological predicate and its context are mutually defining. The psychological predicate (1) marks a significant departure in the immediate context, and (2) implies this context as a background. We have in this relationship the seeds for a model of real-time utterance generation and coherent text formation.

First, when gestures and speech synchronize they jointly form the contrast underlying a psychological

predicate. Second, the form of the gesture embodies the content that makes this differentiation meaningful. These correspondences can be demonstrated by exploiting a quirk in the cartoon stimulus that we have employed, in which Sylvester attempts to reach Tweety by climbing a drainpipe conveniently running up the side of the building from street level to the floor where Tweety is perched; he does this twice – first on the outside of the pipe, then on the inside. If a speaker recalls both attempts and in the correct outside-inside order, the gesture–speech combination relating to the second attempt includes a focus on interiority; this is the differentiating element. If a speaker misses the outside attempt but does recall the inside attempt, or recalls them in reverse order, interiority does not now contrast with exteriority, and the gestures with such recall do not include it as a particular feature. These results have been reported by Susan Duncan at workshops; I summarize them, with illustrations, in McNeill, 2005.

Contexts and Catchments

The context of differentiation is an empirically approachable concept via gestures that organize themselves into ‘catchments.’ A catchment is recognized when one or more gesture features recur in at least two (not necessarily consecutive) gestures. The logic is that a discourse theme will produce gestures with recurring features. These gesture features can be detected. Then, working backwards, the recurring features offer clues to the cohesive linkages in the text with which they co-occur. A catchment is a kind of thread of visuospatial imagery that runs through a discourse to reveal the larger discourse units that emerge out of otherwise separate parts. The recurring features can include hand use (right hand, left hand, two hands similarly deployed, two hands differently deployed), space, orientation, trajectory, hand shape and position, and others, although these are the most common.

By discovering the catchments created by a given speaker, we can see what this speaker is combining into larger discourse units – what meanings are being regarded as similar or related and grouped together, and what meanings are being put into different catchments or are being isolated, and thus are being seen by the speaker as having distinct or less related meanings.

Viv’s Catchments I shall use one speaker’s recounting of an episode from the cartoon stimulus to demonstrate catchments and how they can be used to imply something of the dynamic process of utterance formation.

The episode involves a bowling ball, and follows directly the ascent inside the drainpipe described earlier. Tweety, seeing Sylvester, fetches a bowling ball and drops it into the top of the pipe; the ball and Sylvester meet in the middle; Sylvester shoots out of the bottom of the pipe, the bowling ball now inside him; he rolls, bowling ball style, down an inclined street and into a bowling alley; after a significant pause, there is the sound of pins being knocked over.

Viv’s gesture performance reveals three catchments, recognizable from hand use and hand shape/position:

- C1. The first catchment involves one-handed gestures, and accompanies descriptions of Sylvester’s solo motion, first up the pipe, then out of it with the bowling ball inside him. Thus, C1 ties together references to Sylvester as a solo force.
- C2. The second catchment involves two-handed symmetrical gestures that group descriptions where the bowling ball is the antagonist, the dominant force. Sylvester becomes what he eats, a kind of living bowling ball, and the symmetrical gestures accompany the descriptions where the bowling ball asserts this power.
- C3. The third catchment involves two-handed asymmetrical gestures and groups items in which the bowling ball and Sylvester mutually approach each other in the pipe. Here, in contrast to the symmetric set, Sylvester and the bowling ball are equals differing only in their direction of motion.

With these catchments, we can analyze the real-time origins of the utterance and gesture in the accompanying example, in a way that incorporates context as a fundamental component. The illustrated example is in the symmetrical C2, which shows that one of the factors comprising its field of oppositions was the various guises in which the bowling ball appeared in its role of an antagonist. That is, the idea unit was not only dropping the bowling ball but the bowling ball as a force in its own right. We can write the meaning of the psychological predicate as ‘Antagonistic Force: Bowling Ball Downward.’ This was the context and contrast. Thus, ‘it down’ (see **Figure 3**), unlikely though it may seem as a unit from a grammatical point of view, was the cognitive core of the utterance – the ‘it’ indexing the bowling ball, and the ‘down’ indexing the significant contrast itself in the field of oppositions. And the verb ‘drops,’ therefore, was *excluded* from this GP; it referred to something Tweety did, not what the bowling ball, as a force, did.

Viv’s gesture in **Figure 3** was made with two symmetrical hands – the palms loosely cupped and facing downward as if placed on top of a large spherical object, and the hands moved down during the

Figure 3 Downward stroke with 'it down.'

linguistic segments 'it down.' The inferred GP is this image of downward movement plus the linguistic content of 'it' (i.e., the bowling ball) and the path particle 'down.' The stroke *excluded* the verb, 'drops.' The full utterance was "Tweety runs and gets a big bowling ball and drops it down the drainpipe #]."

The exclusion of 'drops' was not an accident. First, the preparation phase of the 'it down' gesture had two features that skip the verb. Preparation began at the first mention of the bowling ball in the preceding clause (again, preparation for the next gesture began with the object was first mentioned). This shows that the bowling ball was part of the discourse focus at that moment. And, second, preparation continued right *through* the verb, suggesting that the verb was irrelevant to this focus. Further, a brief prestroke hold seems to have preceded 'it down' (although coding varies), which, if present, targeted the stroke to 'it down.' Finally, a poststroke hold lasted exactly as long as it took to complete the spoken articulation of 'down,' which preserved the synchrony of the gesture and the word. So the stroke fully and exactly timed with just two words, 'it down,' and excluded a third, 'drops.' The rest of the utterance can be explained by 'unpacking' this GP via a construction (in this case, the caused motion construction, which provided the verb 'drops' as well as the ground element, 'the drainpipe'; cf. McNeill and Duncan, 2000).

Social Context

Lev Vygotsky, in his argument against Jean Piaget, famously asserted that everything appears in a child's development twice: first on the social plane, later on the psychological (Vygotsky, 1986). The concept of a social-to-psychological transition can be applied to gestures as well. Gestures imply a social other. If one denies access to a listener, the frequency of gesture declines (Alibali *et al.*, 2000). Increasing the number of listeners changes the shape of the gesture space

Figure 4 Gestural mimicry. First panel is a gesture by the speaker to the right; second panel is mimicry by the speaker to the left.

Figure 5 Gesture mimicry synchronized with the other's speech.

and this in turn changes the direction of gestures depicting movements of characters in the story (Özyürek, 2000).

I shall conclude with examples of the social sharing of gestures. The research from which they are drawn is not yet published, but the phenomenon of social sharing or resonance through gesture is significant.

Mimicry and Two-Bodied Gestures Gestural mimicry occurs when one conversational partner, within a short time, reproduces the gesture of the other partner; the effect is often to cement a kind of social solidarity and is accordingly seen commonly between close friends. The example in **Figure 4** from research by Irene Kimbara shows the woman on the left reproducing the gesture just performed by her friend on the right.

A different kind of shared gesture is also possible between strangers. **Figures 5** and **6** are from Nobuhiro Furuyama (2002), who studied the gestures of learners as they were instructed in a new motor task (origami). In each illustration, the learner is seated at the left (two different training sessions). In the

Figure 6 Gesture appropriation synchronized with the person's own speech.

Figure 5 example, the learner mimics the gesture of her tutor. The mimicry occurred without speech by the learner, but her *gesture* synchronized with the *tutor's speech*. As the tutor said "[pull down] the corner," the learner performed the gesture during the bracketed portion. The Figure 6 example, in contrast, shows the learner appropriating the tutor's *gesture* by combining it with her *speech*. The learner is saying "[you bend this down?]," and during the bracketed speech moved her hand to the tutor's hand, and then moved her hand downward and away (the illustration shows the start of the gesture). As Furuyama observes, the tutor had turned in his chair so that the same left-right gesture space was before him and the learner, a maneuver that might have invited her to enter his gesture space. It is striking that any taboo against strangers coming into physical contact was overridden while the hands were in a symbolic mode.

Examples of these kinds address what can be called collectively the 'social resonance' of gesture. Janet Bavelas has long been interested in this phenomenon. Bavelas *et al.* (2000) demonstrated resonance not from the viewpoint of shared feelings, the more traditional approach, but as joint cognition and storytelling; gestural repetition seems to act as grounding and in general conveys mutual understanding.

Gesture: Sociocultural Analysis

J B Haviland, Reed College, Portland, OR, USA

Gesture is Integrated with Utterance

When people come together to interact, they can exploit everything at hand (as we might say) to communicate with one another. They position their bodies in relation to both interlocutors and other copresent people; they manipulate objects in the surround; they orient their senses towards one another; they talk; they look; they listen; and they gesture – they move their bodies (and sometimes other entities as well) as part of interaction. Although this short article concentrates on gestures, mostly those performed with the hands, that form part of spoken utterances, much of what it describes could be extended to a wider range of 'gestural expression,' whether or not linked directly to speech, and including a variety of body parts (head, eyes, face, torso) and corporal techniques.

The keenest observers of human communicative capacities have always been interested in gesture. Consider the expressive postures of clay or stone figurines from Palenque to Phnom Penh, or the fingers,

hands, arms, faces, and bodies of human figures depicted on vases, walls, textiles, shields, masks, and canvases from Auckland to Greenland, or captured in snapshots and sketches from New York to New Guinea. Quintilian, the 1st-century Roman rhetorician, offered a treatise on how to use gesture artfully as part of oratorical persuasion. Grand speculative programs in the 18th and 19th centuries – programs which continue in perhaps less ambitious and explicit forms to the present day – found in gesture evidence for presumed universals in thought and language. Conversely, explorations of human diversity – especially in the 20th century – also found in gesture a fertile empirical ground to demonstrate divergence and cultural specificity. Important here was the rise of iconic recording technologies which allowed observers to reduce fleeting gestural performances to representation which could be indefinitely replayed and scrutinized for analysis. There is a related tension, in both pretheoretical and analytic fascinations with gesture, between nature and culture: between speech-accompanying gesticulation cast as 'pantomime,' 'protolanguage,' or 'natural pidgin' somehow grounded in presumed panhuman iconicity and expressivity, vs.

the unpredictable culturally specific repertoire of gestures that clearly must be conventionally learned, used, and understood, and that remain opaque to non-natives. (Some Los Angeles natives perform an L-shaped hand on their foreheads to mean 'loser,' i.e., to indicate that some third person is a poor excuse for a human being – a gestural convention perhaps no less exotic than the Neapolitan 'hunger' or 'poor' gesture performed with a slapping motion toward the hip – see Kendon, 1992. The 'loser' gesture exists as an animated emoticon on at least one Internet instant messenger service.)

Contrasting bodily movements with other aspects of the utterances of which they form part, the expressive virtues of gesture both complement and differ from those of the digital, segmentable, and structurally contrastive elements of spoken language. Since it uses as an expressive medium the very body that is involved in human action in the first place, gesture can model action both directly and analogically. Even highly stylized pantomimes can illustrate aspects of action not verbally expressed, nor indeed easily expressible: complex configurations of objects and actors, perspectives, details of mechanics and effort in action. Contrasting with the linear flow of speech units, gesture unfolds in four dimensions, and easily combines multiple simultaneous signing vehicles (gaze, facial expression, posture, as well as hands and other extremities) in a miniature and multifunctional orchestra of expression. Utilizing space as well as time, gesture has a dimensionality, a potential persistence, and a spatial immediacy in the context of utterance not similarly available to sound. For example, a gesture can be held across a chain of utterances, thus providing a diagrammatic vehicle to anchor talk; or it can incorporate into a scene spatial elements – such as direction, distance, size, or shape – which receive no corresponding verbal expression.

Nonetheless, gesture and speech characteristically occur together, combining with still other expressive resources to coordinate interlocutors in the communicative process, and often with precise temporal and semantic coordination. Emblems – the culturally specific, learned gestural forms, with usually quite specific conventional readings, like an 'OK hand' or a locally defined obscene gestural imprecation – can cooccur with speech or, perhaps more often, simply replace it, even in the midst of conversational turns. They are thus a kind of language surrogate. Other sorts of gesture, however, seem to be inextricably linked to simultaneous speech. Researchers have repeatedly observed, for example, that depictive or representative iconic gestures – which seem to present images reminiscent of entities or events also receiving verbal mention – appear synchronized with, or

temporally just antecedent to, apparently associated words, or 'lexical affiliates' as they are called. 'Formless' gestures, dubbed 'batons' or 'beats,' seem instead to track speech rhythm, falling at once on stressed syllables and points of presumed speaker emphasis. Furthermore, deictic gestures allow interlocutors to indicate referents spatially (although sometimes in virtual space), and thus provide a (sometimes seemingly indispensable) complement to roughly simultaneous spoken referential expressions, such as *this* or *that*.

Theorists adopt sometimes diametrically opposite positions, however, about the differences between gesture and speech as communicative resources. Some think gesture 'leaks,' betraying a speaker's true feelings and thoughts, perhaps in opposition to more treacherous (because more conscious?) words which may try to conceal them. Or they may see gestures as largely involuntary somatic twitches, simply reflecting the speaker's (or the mind's) struggle to externalize inchoate inner images as a linear sequence of verbal elements. This article will largely ignore the putative 'inner' processes that underlie gestural production, to concentrate instead on the semiotic and functional properties of gestures. We take for granted the communicative potential of gesture in the process of utterance, and its connections with social and cultural formations more generally. For just as gesture is integrated with utterance, tying words directly to a spatiotemporal context, it is also part of wider cultural routines of the body, susceptible both to the stylization and persistence of custom – patterns of gesture have evidently remained largely intact in Naples for several centuries, much longer, no doubt, than patterns of speech – and to the ideological productions of culture to which we turn at the end of the article.

Meanings and Interactions

Gestures function like other signs, verbal or otherwise. To expand on a gestural typology already alluded to, a commonly cited Peircean trichotomy can be applied to gestures. Conventionalized – thus symbolic, in the Peircean sense – emblems, with specifiable 'citation' forms (thus, in Kendon's terms, 'quotable' – 'and then she did **this** [quoting the gesture]') and holophrastic as well as lexemalike meanings, except for their manual modality resemble certain spoken expressions. The conventionality can be seen partly in specific criteria of well-formedness (the circle of the 'OK hand' is made with the thumb and the index finger, with the others extended slightly upwards, not with just any fingers, and presumably not with other orientations of the hand, orientations which in other cultural settings can

produce very different meanings). Conventionality is also evidenced by the families of use to which such culturally specific gestures are put. Indeed, emblems are in both form and function much like interjections, or 'response cries' (Goffman, 1976), which also may depart from the phonotactic canons of a language and which inhabit a characteristic expressive realm – often, for example, indexing various kinds of disapproval or designed for interpersonal social control – but which remain highly culture specific nonetheless.

There are symbolic and conventional aspects not just to a society's repertoire of emblems but to nonce gestures as well. Hand shape in gesture, for example, is sometimes highly specific: how one points, with what digits or other body parts, and what sorts of thing one can refer to with a specific sort of pointing gesture, are matters carefully (and symbolically) regimented in many cultural contexts. In Tepoztlan, Mexico (Foster, 1948), one used different hand shapes to show the height of a table, a donkey, or a child, and using the wrong sort of hand remains a potential insult throughout Latin America. Recent investigation proposes that even in spontaneous gesticulation different hand shapes come in 'families' with highly schematic shared meanings: 'precision' or 'offering,' for example, associated with the 'precision grip' (the touching thumb and index figure of the 'OK hand') or 'open palm' hands, or 'individuation' associated with a lone extended finger. Presumably, however natural the explanations for such groupings may seem, cultural tradition and transmission must be centrally involved in propagating such families of form.

Gestures are also heavily iconic, depicting aspects of objects and actions by selectively mirroring or diagramming shapes, movements, and configurations of entities or events that provide the vehicles for gestural interpretation. A Guugu Yimithirr man, for example, describes how his boat capsized in a storm. He gesturally evokes the rolling motion as the boat was picked up by the wind and tossed on its side (Figure 1), saying "like this." Resemblance is, of course, a feeble principle for interpreting a sign, and interlocutors must always infer what aspects of a demonstration they are to attend to – one reason that words and gestures frequently complement one another semiotically, or that gesticulation uninformed by the accompanying words may remain obscure, until the soundtrack (or the subtitles) are turned back on. Because gestures iconically – if schematically – demonstrate actions and depict objects, they can also incorporate varying perspectives or viewpoints on such action, often more directly than can syntactic and lexical devices which imply voice or valence. A gesturing hand can represent now an object, now

Figure 1 First shipwreck gesture.

a tool for operating on it, now an actor manipulating it, and now an observer of the scene. Gesture can also suggest granularity or resolution (for example, in gestures accompanying directions or instructions), as well as specifics of the configuration and shapes of objects – a principle exploited in sign language nominal classifiers, and used to advantage in spontaneous gesticulation as well. A hand holding even an imaginary object adjusts itself to its shape and weight.

Finally, gestures indexically project the contexts of their occurrence. The rhythmic gesticulations called beats, mentioned above, are almost pure indexes, tracking the speech stream much in the way a conductor tracks a score, and additionally parsing it into significant segments. Even the most wooden of gesturers – from Englishmen to presidential candidates – seem to punctuate their syllables gesturally. However, the observed synchrony between gestures in general and their apparently affiliated words is itself an indexical trace of the temporal unfolding of an utterance. A pointing movement, another classic indexical sign, may pick out a perceptually available referent, but it may also create an invisible one in thin air, leaving it available for later resumption by gestural (or spoken) anaphor. Clark (2003) describes a range of object manipulations, which he calls 'placing,' to achieve referential ends parallel to those of 'pointing.' Crucially, gestures of 'placing' depend for their success on the structure of space – and of particular culturally significant spaces (from store counter tops or queues, in Western society, to the hearth or the notorious witchcraft cave in, for example, indigenous Mexico).

Pointing gestures are of particular interest because they combine all the Peircean modalities and additionally require careful conceptual coordination between interlocutors to convey their meanings.

Figure 2 Double pointing gesture.

Consider the case of Rosa, in **Figure 2**, who makes a complex double pointing gesture, when she reaches the climax of a story about an elderly woman who opened the downstairs door of her house to some threatening men. Afraid, she wanted to escape out the same door, but could not because she had left the upstairs door to the house itself unlocked. In Friulian, Rosa narrates the older woman's dilemma in the present and in the first person: "*Nopos la vie parze che o ai lepuarte viarte* [I cannot leave because I have the door open]." She performs the double pointing gesture in two stages: her left hand reaches out with the fingers extended loosely to the right when she says "I cannot leave"; then her right hand – which has accompanied the other in the move to the right – forms a pointing hand and points up to her left as she says "the door open." The gesture invokes diagrammatically the configuration of the house (an outside door to stairs which lead up to the main dwelling) which Rosa's audience knows well. It indexes the relevant locations in that conjured space. Rosa uses conventional index finger pointing to signal the unlocked door, and a looser pointing hand to show the blocked escape route. And, interactionally, the double point captures perfectly the protagonist's dilemma: a choice between two impossibilities.

Directional indexicality also infects gestures otherwise based on quite different semiotic principles. A gestural imprecation, for example, can be performed in a specific direction, indexing at once its target and its author. A depiction can combine the

Figure 3 Second shipwreck gesture.

representation of a referent's size with an indexical indication of its position. In the shipwreck example mentioned above, the gesture not only illustrates the boat's rolling motion but also indexes the cardinal direction in which the boat flipped over, given prevailing storm winds. Contrast **Figure 1**, where the speaker has north to his right, and shows the boat flipping in front of him, i.e., to the west, with another performance of the same story where the narrator is facing north, and depicts the boat flip with a very different motion, but in the same direction (see **Figure 3**). Indeed, the shipwreck gesture illustrates a perhaps unexpected sort of gestural convention, since it is a norm for speakers of Guugu Yimithirr (and in other communicative traditions, too) that gestures depicting motion, real or hypothetical, remain faithful to cardinal orientation (Haviland, 1993).

Though most research has concentrated on gestural 'meaning,' gestures (along with attitudes of the body more generally) are clearly central in coordinating (inter)action. The preconditions of face-to-face communication involve positioning bodies to allow, restrict, or prevent mutual access. Moreover, states of

talk can be restructured and reorganized in part by the talk itself, and in part by reorientations of interlocutors brought about by gesture, shifts in gaze, and adjustments of posture. Theories of the ontogenesis of gesture often link children's manipulation of objects as the source for later gestural 'ritualization.' Pointing, for example, appears to grow out of grasping and reaching. Even in adults, handling objects, moving them, and directing attention to them and to the spaces around them seem to give rise to gestural routines which, in turn, can become routinized or 'grammaticalized' through the course of an interaction. Gesture is thus embedded in bodily techniques, themselves notoriously shaped by cultural practices.

Ideologies of Gesture

Like other cultural practices, gesture when it rises to explicit consciousness inspires metatheory and ideology. The most astute early students of gesture, from de Jorio to Efron, comment with skepticism on theories which purport to link the proclivity to gesture, or gestural exuberance, to aspects of personality or temperament, if not to gentility and good breeding, or even to race and national character. The fact that such links have been advanced, nonetheless, suggests something about an ethnotheory of the communicative economy which gesture and speech jointly inhabit. The fact that some populations – ranging from Warlpiri women in mourning, who must not blurt out certain tabooed words (Kendon, 1988), to members of monastic orders who abjure the worldliness of words – voluntarily substitute elaborated, conventionalized systems of gesture for speech, is a kind of reversal of the common injunction on children in other societies not to point or impolitely overuse their hands in talk.

Arguments about the communicative virtues of gesture seem always to involve subtle and perhaps contradictory ideological stances: Roman orators (like modern-day politicians) hoped to become more persuasive through calculated use of gestures; but pop psychologists argue that 'body language' is truer – precisely because deeper and less susceptible to conscious manipulation – than words. Some theories find gestures peculiarly appropriate to situations where words fail – over great distance, or in situations of too much (or too little) noise; others find virtue in their surreptitious and silent potentialities (as in the case of the Cuna lip point [Sherzer, 1972], which can be a vehicle for clandestine criticism or mockery). Finally, the analytical debates about whether gesture is a speaker's or a hearer's phenomenon (i.e., whether

it is, in the psychologists' parlance, 'communicative') reflect pernicious dichotomies that surround such culturally specific notions as volition and intention, individual vs. community, or knowledge/mind vs. practice/body.

Gestures: Pragmatic Aspects

J Streeck, University of Texas, Austin, TX, USA

© 2006 Elsevier Ltd. All rights reserved.

(Hand-) gestures play many diverse roles in human life and do many different jobs in social interaction. Gesture – simple emblems like the thumbs-up sign as much as ongoing gesticulation that accompanies talk – is a most flexible resource that is utilized in a multitude of cultural practices, ranging from legal proceedings to work in mines to the making of music and intimate moments of talk, and it is always in play when people collaborate with their hands on common tasks. The practices of gesture are heterogeneous and difficult to subsume under a common denominator, other than that the activity involves communicative action of the hands. The view adopted here is focused by the question how gesture serves persons – *embodied actors* – who are acting in the world together, within specific ecological and cultural settings, and together making sense of it; gesture is conceived as a mode (or set of modes) of bodily action by which the world is structured, known and understood, not in the first place as a system of signs or a mode of expression.

Gesture serves human activities, including conversation, in a number of different capacities that can be conceived as *alignment-types*: ways of aligning people, gesturing hands, and the situated world within which they interact. Alignment types are distinguishable on the basis of the framework of participant orientation within which gestures are perceived and understood, i.e., in terms of their alignment and coordination with gaze, speech, action, and the setting or landscape within which the interaction takes place. Six alignment types are distinguished here, leaving open the possibility that there are others:

1. hand gestures can aid in the structuring and making sense of the **world-at-hand** (i.e. the world **within** reach of the hand);
2. they can serve for orientation within and understanding of the **world-within-sight** (but **beyond** reach of the hands);
3. gestures can represent or **depict** the world in its absence, within the 'gesture space' (McNeill, 1992) that is created by the participants' orientation to the gesturing hands;
4. hand gestures, often in combination with other bodily action, can **embody communicative action** and discourse structure;
5. they can **mediate and regulate transactions**; and
6. they can construe content that is conveyed by the verbal utterance that they accompany (*ceiving/ception*).

In the following, the features of each alignment type are described, and gestural practices that are characteristic of it are discussed. The last section of the article delineates aspects of the coordination of gesture and speech.

Making Sense of the World at Hand

A great deal of inconspicuous gesturing occurs while people and their hands are actively engaged with the world at hand. Gestures arise as a byproduct of and in the service of practical action, disclosing features of the immediate scene, or otherwise involving the touching, feeling, grasping, and handling of whatever is at hand, and maybe the making of something from it. Gestural practices that are coupled with the world at hand are often excluded from the study of gesture, which is treated as movement in the air by empty hands. However, wherever cooperation involves the handling or making of things (including the making of graphic marks on paper), one finds manifold indexical, iconic, and symbolic actions of the fingers and hands, and often these are entirely indispensable, given the type of activity underway and the communication tasks that it raises for the practitioners (Ochs, Gonzales *et al.*, 1996).

Among the 'jobs' that gestures do in the world-at-hand are: to structure the participants' perception of objects; to disclose intrinsic, invisible features and affordances of things; to analyze, abstract, and exhibit action; and to 'mark up' the setting. Gestures can arise as minimal modulations of instrumental acts, performed for the benefit of the coparticipants, e.g., in the context of demonstrations.

Genres of gestural practice found within the world-at-hand include, among others:

Tracing: An index finger, set of fingers, or hand is moved along a surface, thereby drawing a line, but also gathering tactile information, in order to discover (feel), disclose, and broadcast undisclosed features of objects or to inscribe real or imaginary marks on surfaces (e.g. to suggest possible features and fields of action). Goodwin writes:

A quite general class of cognitive practices consists of methods used to divide a domain of scrutiny into a figure and a ground, so that elements relevant to the activity of the moment stand out. ... Through these practices structures of relevance in the material environment can be made prominent (Goodwin, 1994).

Exploratory procedures (see Gibson, 1962): These are patterned actions by which hands systematically explore intrinsic object properties (texture, volume,

consistency, temperature, brittleness) and affordances (what can be done with objects). While these actions serve the information-gathering needs of the actor, they are easily enhanced so as to disclose, i.e., make visible and broadcast, the qualities that are discovered through them. Demonstrative haptic or tactile explorations provide for shared understandings of the material features and functional characteristics of the things that require our attention.

Highlighting action and its accessories: Practical actions or their stages are elaborated through formal operation such as exaggeration, repetition, and segmentation, to disclose their logic, components, and characteristics to coparticipants. Gesturalization serves as a method for the self-explication of manual action. Minimal modifications – e.g., the repetition or exaggeration of a component act – can serve to draw attention to stages or accessories of the activity.

When the participants employ artifact-based representation practices (e.g., writing, diagramming, doodling) in addition to speaking and gesture, as is common in many lines of work, gesture can become aligned and enmeshed with them (Streeck and Kallmeyer, 2001), which can result in hybrid symbolic acts (e.g., symbolic gestures committed to paper, a line drawn on paper to emphasize a currently spoken word); situated, ephemeral graphic artifacts such as doodles and/or the acts of making them thus take on social-symbolic functions. Gesture is also indispensable as a medium for the interpretation of professional diagrammatic representations: architectural and engineering blueprints, for example, are enhanced by gestures showing motion, changes over time, or the dimension of height that the flat diagram lacks.

What distinguishes this entire variety of gesture uses from other basic varieties is their alignment within the material, perceptual, and cognitive ecology of the situation: they are perceived and understood by reference to their contiguity with objects and instrumental acts. In other words, the participants' visual attention encompasses gestures and things, and these elaborate one another. Gesture directs the recipient's attention, an effect that is also achieved by the placing of objects in the recipient's line of regard. Gesturing about and arranging objects are activities that serve epistemic functions and often go hand in hand (Kirsh, 1995).

Revealing the World within Sight

A different framework of person-gesture-world alignment is realized when the gesture orients the participants to the visible world beyond the reach of the hands. This is the prototypical realm of pointing: an extended index finger or hand (or another array of body parts whose constellation can be seen as

a vector) enables the participants to coordinate their orientation so that they jointly focus their gaze on a distant object, feature, or location. Pointing is only one type of orienting behavior, however; posture, gaze direction, and head orientation can serve similar purposes, as can the placing of an object in the interlocutor's line of regard (Clark, 2003). And pointing is not universally executed with an extended index finger (Wilkins, 2003); other varieties include lip-pointing (Sherzer, 1972) and pointing by gaze and movements of the head. Within a given repertoire, there may also be pragmatically motivated alternatives such as pointing by index finger – to individuate an object among other objects – and pointing with the open hand – to select an object as an exemplar of a kind (Kendon and Versante, 2003). Handshape and motion patterns can also serve to **characterize** the focal object, i.e., to shape the recipient's perception of it. Gestures made in this mode serve spatial orientation as well as the sharing of sights: once a shared visual focus is established, what is seen together can then be structured by gesture; motions of the fingers and hands project lines, vectors, points, etc., onto seen scenes, indicating **how** what is visible should be regarded. The visual field – i.e., the culturally structured landscape within sight – is thus augmented and made intelligible by layers of cognitive-manual actions and forms.

Depiction by Hand

The third alignment type of hand gestures is brought about when interaction participants turn away from the world and focus attention inside their interactional huddle, and, by their bodily orientation and positioning in space, mark off the space between them as territory of their interaction. The interaction space becomes the stage for hand gestures when attention is, however fleetingly, focused on the speaker's gesticulating hand(s) (Streeck, 1993). This happens whenever gesture is employed as a representation device, to depict aspects of the talked-about world, whether concrete or abstract, real or imagined. When gesture is used to depict or represent, for example in the context of narrative, recipient attention is solicited for the gesturing hands. This is done, for example, by including deictic expressions in the talk, some of which, for example deictic adverbs (Spanish *asi*, German *so*), seem to be primarily designed for this task. In the context of depiction, gesture is a foregrounded activity. Descriptive (depicting) gestures represent worlds in collaboration with speech, and they are understood by reference to what is **known** about the world, not what is seen at the moment.

While the category 'iconic gestures' is a familiar one, the actual study of gestural depiction is in its

infancy (but see Müller, 1996; Kendon, 2004). The most detailed accounts describe iconic devices in sign languages of the deaf (Mandel, 1977), which however operate under different conditions and carry different representational loads; they function in part by virtue of their paradigmatic relations to other signs within large, conventionalized repertoires. Practices by which worlds are depicted on the gesture stage include the placing of imaginary objects on the stage; diagramming relations between them; enacting practical action schemata; sculpting volumes; and drawing outlines, among others. Some of these representational practices may be derived from other cultural practices (e.g., from drawing in sand). Most important, because most readily available to the hands, are acts of virtual grasping and handling, by which objects and instruments are evoked.

When complex imagery is assembled over time, as is the case when complex objects or events are described, the two hands often complement one another: one may 'hold' and classify the object, the other supply additional characterizations or arguments (Enfield, 2004). Repertoires of routinized and sometimes specialized methods of gestural depiction are part of the tacit communicative skills required by various professions, including designers and engineers.

Gestural depiction does not work by virtue of the hands producing shapes that **resemble** real-world phenomena, but rather because in a given context an action of the hand can be seen as **characterizing** a phenomenon or experience, and much as any phenomenon can be characterized by a multitude of words, it can be characterized by a multitude of gestures. Often, although essential to the success of the communication, the representational load of a gesture is minimal, because it is embedded within rich linguistic descriptions, and all it must do is to evoke a single feature for the practical purposes of the activity at hand (Arnheim, 1969).

Embodying Speech and Communicative Action

Another alignment type and functional genre of hand gestures that is common in the context of conversation, but also occurs interwoven with gestures of other alignment types, is the use of the hands in the embodiment of communicative action. This includes gesturing by which the communicative act performed (question, proposal, imploring, and so on); aspects of the pragmatic and syntagmatic structure of the unfolding utterance; and coherence relations between successive or separate utterance parts are shown or foreshadowed. A minimal version of this mode of gesturing are beats, i.e. hand movements characterized

less by a distinct handshape or form than by repetitiveness and emphatic synchronization with the rhythm of speech, and signifying not so much by form as by changes in form which cue the beginning of a new speech unit. The pragmatic mode of gesticulation also includes pronominal referential gestures: pointing-like motions, often made by the thumb, which individuate and refer figuratively within the universe of discourse, marking acts of reference to nonpresent people, locations, or points in time. And it includes the display of the stance that the person takes towards an utterance or the content expressed. Pragmatic gesture encompasses all actions of the hands (and a variety of other body parts, notably the face, head, and shoulders) by which aspects of the communicative interaction are displayed. The category also includes recipient actions, such as head gestures of affirmation and negation or rejection that are known throughout human societies. Speech act gestures (gestures that embody illocutionary force) often possess metaphorical quality: they figure aspects of the processes of speaking and communicating as handlings of physical objects or as conduit (McNeill, 1992) (*see Speech Acts and Grammar*).

The characteristic alignment of pragmatic gesturing is its occurrence at the periphery of the interaction space: such gestures are commonly executed outside the line of sight of the speaker and at the periphery of the visual range of the addressee. They are rarely subjected to the speaker's visual control. While this is the unmarked way in which communication is embodied, occasionally pragmatic gestures are made salient by being performed in the segment of the interaction space that is usually reserved for gestural depiction. Generally during conversation, the embodiment of speech and communicative action and process by hand gestures is a background process. But pragmatic gesturing is also the most ubiquitous, irrepressible, and perhaps indispensable variety of gesture, contributing greatly to the precision timing and entrainment that are characteristic of so much conversational interaction. Many societies have conventionalized at least some pragmatic gestures; some, such as that of southern Italy (Kendon, 1995), have evolved large repertoires (de Jorio, 2000 (1852)). Yet we also find immense individual variation in pragmatic gesturing; individuals tend to evolve habitual personal styles of gesticulation, and these idiosyncrasies are most obvious in pragmatic gesticulation.

Ordering and Enabling Transactions

Gesticulation in the pragmatic mode overlaps to a large extent with another usage variety; possible differences in alignment, however, suggest that it be

treated as its own kind. This is gesticulation, that is also occupied with the communicative process, but at the same time addresses other interaction participants whose actions it is intended to regulate. This mode of gesturing can involve touching the other (Efron, 1972 (1942)), thereby eliciting attention or allocating a turn, soliciting response or attempting to silence it, and directing the attention of others to one another, among many other interactive and social-organization functions that these gestures serve. Many gestures blend the display of communicative action with the regulation of the behavior of others, and the distinction between these two modes is of only limited analytic value: at one end of the polarity, gestures are aligned with what the speaker is presently doing, and convey something about it; at the other end, they are performed in attempts to structure the actions of other participants. Often a gesture is aligned in both ways at the same time, or the two functions are realized at different points within the same gestural action.

Interactive or transactional gestures have enabled the development of codified, specialized gesture codes by which complex transactions such as vehicular traffic (the gestures of traffic cops), legal proceedings (as in medieval codes of law), or the making of music (through the gestures of conductors) are ordered or accomplished.

'Ceiving'

The last mode of gesturing included here is not usually treated as a distinct mode, but rather as the paradigmatic form of all gesturing other than pointing; however, it is easily distinguished in terms of the way it is aligned with the interaction participants' lines of regard as well as the current state and progress of talk. This is a mode of gesturing that is adequately described as 'thinking by hand': it involves the speaker's hands producing schemata in terms of which utterance content or narrated experience is construed. This mode is usually lumped together with gestural depiction (under the label 'iconic gesture'); however, although 'ceiving' or 'ception' is usually a component or means of gestural depiction (as well as of pragmatic gesticulation), it also occurs on its own, within an alignment framework that is different from both gestural depiction and pragmatic gesticulation. The 'pure' variety of ception is realized whenever speakers, **without attending to the process**, use their hands to give form to – i.e. construe – content. Often this is done via a simple or complex schema of grasping – by means of a prehensile posture (Napier, 1980), which is why this author labels it 'ceiving' or 'ception' (from Lat. *cap-*, take; a pattern thus formed is called a 'cept'). Ception is a bodily form of conceiving,

i.e., of conceptually structuring content to be articulated in speech: this content-to-be-made-sense-of is **grasped** by an abstract prehensile action (the grasp occurring 'in the air').

The notions of ceiving/ception and cept that are introduced here are predicated upon a view of thinking as an activity not of the mind or brain but of the entire person, involving the body and its cultural skills in relevant ways, and of grasping by hand and other modes of handling objects as primary human forms of exploring, recognizing, and understanding the world, activities which provide numerous models after which linguistic concepts are formed, including the concept 'concept' itself, which depicts the process of making-sense-of (conceiving) as 'taking-hold-of-together,' i.e., as action by the hands. In ception, thinking-for-speaking draws upon the intelligence and world-knowledge of the hands. In contrast to depiction, during which the speaker **controls** the activity of the hands, during ception the speaker is **dependent on** his or her body to 'come up with' an appropriate cept: the process of speaking becomes dependent upon embodied knowledge. Thus, when we observe speakers forming cepts while speaking, we witness the very process of embodied thought. Cepts, of course, are also formed and used during acts of depiction, in which case they depict phenomena in terms of ways of grasping or handling them. And many pragmatic gestures – metaphorical ones – are ceivings and articulate the process of communication as a handling of things (see **Pragmatic Acts**).

The extent to which speakers rely on 'pure' ceiving (i.e. ceptional activity of the hands performed outside the realm of conscious awareness and without specific depictive aims) to aid them in the formulating of talk and the making of sense appears to vary greatly. When the activity occurs, however, it is easily recognized: it involves the speaker orienting to the interlocutor, not to the gesture (ceiving is a background process), and performing largely haptic motions whose gestalt often coincides with subsequently uttered concepts. When interlocutors see the speaker actively searching for a concept (i.e., a word), they may volunteer one that fits the cept that the speaker has presented. In other words, listeners have privileged access to the speaker's gestured cepts (which is *not* the case during depiction).

Pragmatic Function and Placement of Gestures

Word searches demonstrate the importance that the relative ordering of gesture and speech has for the process of intersubjective understanding: during

ception, manually performed cepts usually precede verbally articulated concepts. The hands are given an opportunity to find the first form that makes sense. Interlocutors are thereby afforded previews of concepts, enabling them to build understanding incrementally. Within the context of the other alignment frameworks, relative ordering of gesture and talk is organized differently and meets different tasks. When gesture is engaged with the world-at-hand, talk is often subservient to and made to fit the manual-visual procedures by which the scene is illuminated and its perception shaped. Pointing is coordinated with specific classes of linguistic expressions (deictics and demonstratives) (see **Deixis and Anaphora: Pragmatic Approaches**). During depiction special linguistic expressions and gaze direction are used to direct the recipient's visual attention to the gesture; gaze, talk, and gesture are orchestrated with great precision to render multimodal representations of worlds beyond the interaction space. Embodiments of communicative action, in contrast, and many other-directed, interactive, or transactional gestures are background processes, perceived peripherally (by listeners) or kinesthetically (by speakers), and providing an ongoing interactional framing and footing of the talk that occupies the focus of attention. Very important for the functions of pragmatic and interactional gestures, on the other hand, is their exact placement within the turns and sequences of interaction within which they occur (see **Conversation Analysis**). Gestures made just prior to or during the initiation of an utterance can foreshadow the speech act for which the turn is taken; ongoing gesticulation in mid-turn can mark the continuing relevance of the speech act frame of the turn, or the performance of a series of such acts, for example during extended turns at talk; and gestures made during or after utterance completion can indicate the kind of response that is sought for it, or the stance that the speaker takes with respect to what is conveyed (as is the case with shrugs, which are common during utterance completion).

All gesturing of the hands is co-orchestrated with speech prosody: gesture units coincide with prosodic units, and gesture strokes are coordinated with prosodic stress. In some specialized varieties (the gestures of rappers and conductors, for example), but also sometimes during ordinary conversation, gestural motions appear to map out the movement of the voice, thereby visualizing acoustic phenomena. To some extent, this coordination is a by-product of the self-synchrony of the human body: muscular actions of the limbs synchronize with muscular action of the vocal apparatus. At times, however, the hand's dancing to the vocal beat is a more deliberate practice of revealing the ongoing organization of speech,

offering the recipient hand-packaged 'chunks' of talk by providing coherence via rhythmically placed iterations of a gestural act.

Goffman, Erving

J Léon, CNRS, Université Paris 7, Paris, France

© 2006 Elsevier Ltd. All rights reserved.

Erving Goffman ranks among the most celebrated sociologists in the world of the second half of the 20th century. His work ranged from urban anthropology to sociolinguistics, ethnology of communication, and microsociology with the study of social interaction. In spite of this diversity and his own refusal to subscribe to any particular trend, he is generally placed in the symbolic interactionist paradigm of sociological thought (School of Chicago).

Erving Goffman was born in 1922 in Manville (Alberta, Canada) of Ukrainian Jewish parents and spent his childhood in the Ukrainian Jewish community of Dauphin, near Winnipeg. He began studies in chemistry at the University of Manitoba in Winnipeg and worked at the National Film Board, in charge of propaganda documentaries, led by John Grierson. In 1945 he received a degree in sociology at the University of Toronto, following the teaching of the anthropologist Ray Birdwhistell, who taught that gestures, just as with institutions and social facts, are accountable of sociological analysis. After he got his M.A. in 1949 at the University of Chicago, with Everett Hughes, he was appointed research assistant at the University of Edinburgh, where he met Tom Burns, one of the leaders of British sociology. He spent more than 2 years (1949–1951) in one of the Shetland islands to gather material, based on the observation of conversational interactions, for his PhD thesis which he submitted in 1953 under the supervision of Lloyd Warner at the University of Chicago. From 1954 until 1957, he was a visiting scientist at two psychiatric hospitals, the National Institute of Mental Health in Bethesda, Maryland, and St. Elizabeth Hospital in Washington, D.C. From this experience he published *Asylum* (1961).

From 1958 to 1968, he held teaching positions at the University of California, Berkeley: visiting

assistant, assistant professor, and eventually professor of sociology. From 1968 to 1982, he was offered the prestigious chair Benjamin Franklin of Anthropology and Psychology at the University of Pennsylvania. In 1981, he was elected President of the American Sociological Association. He died of cancer in November 1982 in Philadelphia.

Goffman was a part of the linguistic turn of the 1950s and 1960s, making significant contributions to linguistics by undertaking formal study of talk and developing the notions of public, self, face, demeanor, structures of attention and information, ritual, footing, and frame. His work is characterized by the interplay of concrete data and theoretical development and by the use of the metaphors of theater and stage management to draw attention to the manipulative and the moral aspects of social life.

From the time he wrote his dissertation (1953), Goffman was concerned with face-to-face interaction, and he implemented it in a formal linguistic way in his last works, *Frame analysis* (1974), *Forms of Talk* (1981), and the paper 'Felicity's condition' (1983a). Through the notions of response, footing, and frame, Goffman strengthened the connection between discourse analysis and conversation analysis. Opting for microanalysis as a method of study, he accounted for the ways in which the situatedness of speech contributes to the form and meaning of utterances, and he analyzed the procedures employed by people in their face-to-face dealings with one another. With his notion of footing, Goffman analyzed the structure of communication in social encounters. He made analytic distinctions by assigning different kinds of participant roles to hearers (the participation framework), either addressee, overhearer, or eavesdroppers, and to speakers (the production format), either animator, author, or principal. It is linguistics that provided the cues and markers to determine such footings. Levinson (1988) developed this topic in proposing a set of universal participant categories based on grammatical grounds.

It should be mentioned that when Goffman was at Berkeley, he worked on telephonic conversations with Garfinkel and Sacks while visiting them in 1963 at the Center for the Scientific Study of Suicide in Los Angeles. However, Goffman's views diverged from conversation analysis on several issues. He found it unnecessary to incorporate recorded data in his work and to analyze detailed actual interactional events. While conversation analysts use turn-taking organization, adjacency pair, and the organization of repair to deal with interaction, Goffman promoted the notion of face both as an account for action and as the motivating basis for the ritual organization of interaction. Finally, for Goffman, talk was not transparent, and conversation relied heavily on presuppositions and not on the sole turn-taking system claimed by conversation analysts.

It must be added that Goffman was an authentic stylist and that his books, noticed as early as 1959 with the publication of *Presentation of self in everyday life*, continue to be widely read outside of the restricted field of sociology. His writings, available in many languages, include eight books, three collections of essays, and at least 28 essays. His last book, *Forms of talk* (1981), was nominated for a National Book Critics Circle award in 1981.

Grice, Herbert Paul

P P Chruszczewski, University of Wrocław, Wrocław, Poland

© 2006 Elsevier Ltd. All rights reserved.

(Herbert) Paul Grice was born on March 15, 1913 in Birmingham, England, into the family of Herbert and Mabel (née Felton) Grice. His father was a successful businessman who manufactured small metal items. Herbert Paul was educated at Bristol Clifton College and at Corpus Christi College at Oxford University. While in college, Grice combined the study of classics with philosophy and later became a lecturer in

philosophy at St. John's College, where he was elected a fellow in 1939. During World War II, Grice served his country in the Navy, first in the North Atlantic, then from 1942 in Navy Intelligence at the Admiralty. After his military service, Grice returned to Oxford's St. John's College. At the end of 1967 he left for the University of California at Berkeley, where he taught and conducted research, obtaining full professorship in 1975. In 1980 Grice retired from his university position, but remained active in pursuing his linguistic and philosophical investigations.

Paul Grice is generally known for his two most influential papers, 'Meaning,' published in 1957,

and 'Logic and Conversation,' published in 1975. In 'Meaning,' he distinguishes between two types of meaning: (1) the 'natural' or 'observable' meaning and (2) the 'nonnatural' meaning, that is, the idiosyncratic meaning of a particular communicator. In 'Logic and Conversation,' Grice argues that in order to communicate people need to cooperate while exchanging verbal information and proposes the 'cooperative principle'; "Make your conversational contribution such as is required, at the stage at which it occurs, by the accepted direction or purpose of the talk exchange in which you are engaged" (Grice, 1975: 45).

The Gricean cooperative principle is subdivided into context-related maxims. According to the maxim of quantity, one should provide the listener with just the needed amount of information. The maxim of quality states that one should produce only texts that one believes to be true. One needs also to be relevant while communicating with others; and last but not least, one should communicate in a particular manner, that is, express oneself verbally in a clear way. Grice is probably best known for presenting an idea of 'conversational implicature' in terms of this theory. For example, let us suppose that A informs B, "I'm cold," and B replies, "Here is a blanket." B's reply, by offering the blanket, is a proper response to A's conversationally implicated request to B to do something about A's being cold.

Grice is also regarded as the father of 'intention-based semantics,' in which the phrase 'timeless meaning' (i.e., conventional meaning) is of fundamental importance. As Gaukner explains, "That a certain form has a timeless meaning is normally necessary if a speaker is to reasonably expect that an utterance

of that form of words will produce the intended effect" (2004). Grice's works helped establish pragmatics as the study of meaning embedded within its context. His impact is felt in many branches of contemporary linguistics, including the study of communicational grammars of discourses, conversational analysis, and even axiology.

Guillaume, Gustave

J Hewson, Memorial University of Newfoundland, St. John's, NF, Canada

© 2006 Elsevier Ltd. All rights reserved.

Gustave Guillaume was born December 16, 1883. His early education remains obscure, but in 1914 he became a student of Antoine Meillet (1866–1936) at the Ecole des Hautes Etudes in Paris, at Meillet's invitation. In 1919 he published *Le problème de l'article et sa solution dans la langue française* (awarded the Prix Volney), the first extensive examination of article function; articles are actualizers, which when added to an underlying noun, or noun in tongue

(i.e., *langue*), create a surface noun phrase, or noun in discourse ((discourse) replaces Saussure's term 'parole').

In 1929 he published *Temps et verbe. Théorie des aspects, des modes et des temps*, in which he presented verbal systems as cognitive systems having successive developmental stages, which can be detected by complexity of form and surface usage. Language is no longer seen as static, but as an activity, the creation of discourse. In 1931 he became vice-president of the Société Linguistique de Paris, and in 1934 its president.

Subsequent to the death of Meillet, he was appointed lecturer at the Ecole des Hautes Etudes in

1938, and taught there until his death in February, 1960. The classes had a regular clientele, some of whom attended year after year. During these 22 years, he further developed the view that a language is a cognitive structure, in which content is primary, and morphosyntax, since its only role is to make the content perceivable, is secondary. His Law of Coherence states that a content system (e.g., nominal number) is fully coherent, so that irregular plurals (e.g., mice, teeth) are just as regular in their cognitive content as other plurals. His Law of Simple Sufficiency states that the morphosyntax easily tolerates irregularity; it only has to be regular enough to reflect sufficiently the coherence of the content system that it marks. He also developed his views on the act of language, the cognitive activity of the speaker in creating discourse, a study to which he gave the name of 'psychomechanics,' since it deals with mental mechanisms.

Towards the end of his life, he published one book and some 20 articles, gathered into a posthumous volume (1964). In his last decades his ideas began to be disseminated by others, notably Moignet, Stefanini, Molho, in France, and Roch Valin in Canada. On his death he left his papers, including the draft text of every lecture given during the 22 years at the Hautes Etudes, to Valin, who subsequently founded the Fonds Gustave Guillaume at Laval University in Quebec City as a research center in psychomechanics. By 2000, 16 volumes of the lectures had undergone joint publication in Canada and in France, with another 19 still to come. A volume of important excerpts has also appeared (1973); it was translated into English

(1984), and then into half a dozen other languages. In 2003 an important manuscript that he had completed just before his death was published: *Prolégomènes à la linguistique structurale 1. Essais et mémoires de Gustave Guillaume*, a profound and coherent presentation of his linguistic thought, with a second volume in 2004, which also contains notes for two further volumes that he had planned. There are further volumes to come, and the fact that the value of these is undiminished after almost fifty years is an indication that Guillaume was a most original penetrating thinker, as recognized by his faithful audience at the Hautes Etudes (many of whom had distinguished careers of their own).

H

Habermas, Jürgen

J Maat, Universiteit van Amsterdam, Amsterdam,
The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Jürgen Habermas is one of the foremost social theorists and political philosophers of postwar Germany. He was born in Düsseldorf on June 18, 1929, and grew up in the town of Gummersbach. In the autumn of 1944, at the age of 15, he was sent to the front to serve as an assistant in the sickbay. He returned home in February 1945, three months before the final collapse of the Third Reich. Finishing his secondary school in the following years, he learned to appreciate the 'bourgeois constitutional state' as a historic achievement. He went to the University of Göttingen in 1949, spent a short period studying in Zürich and moved to Bonn in 1950, where he studied philosophy, history, psychology, German literature, and economics with Erich Rothacker and Oskar Becker. In a newspaper article published in 1953, he exposed Heidegger's association with Nazism. After obtaining his Ph.D. in 1954, he worked as a journalist. He married Ute Wesselhoeft in 1955; they had a son and two daughters. In 1956, Habermas became a research assistant to Theodor Adorno at the Institute for Social Research in Frankfurt, which was led by Adorno and Max Horkheimer. Thus involved with the Frankfurt school of philosophy, he developed a neo-marxist critical theory of society, which emphasized the importance for democracy of a public debate that is undistorted by financial and administrative powers. Because of a conflict with Horkheimer, he resigned in 1959 and managed to get a scholarship to finish the thesis for his second doctorate (Habilitation), which he obtained in 1961 under the supervision of Wolfgang Abendroth (*Strukturwandel der Öffentlichkeit*, 1962). At the recommendation of Hans-Georg Gadamer, Habermas was appointed professor of philosophy at Heidelberg in 1961. Taking sides with Adorno in the so-called 'Positivismusstreit,' he argued against Popper's critical rationalism that a critical social theory differs essentially from natural science. He stayed at Heidelberg until 1964, when he had the opportunity

to become professor of philosophy and sociology at the University of Frankfurt. In the following period, he further established himself as a leading intellectual, whose views were influential, though not uncontroversial, in the student protest movement of the late 1960s. In this period he also traveled to the United States, where he held various visiting positions.

Habermas left the university in 1971 to become co-director, with Carl Friedrich von Weizsäcker, of the 'Max Planck Institute for research of the life conditions of the scientific-technical world' at Starnberg. During this period, he initiated a research program that he has been pursuing for the rest of his career, and which centers around communicative action. In 1981, he published his magnum opus, the 2-volume *The theory of communicative action* (Habermas, 1981). In 1983 he returned to the University of Frankfurt, where he once again became professor of philosophy. This period was marked by his vigorous defense of the emancipatory potential of modernist thought against the attacks by postmodernist, deconstructivist thinkers (*The philosophical discourse of modernity*, Habermas, 1985), and by the elaboration of his theory of communicative action in the field of ethics (*Justification and application: remarks on discourse ethics*, Habermas, 1991) and philosophy of law (*Between facts and norms: contributions to a discourse theory of law and democracy*, Habermas, 1992). After his retirement in 1994, he continued to write influentially on a number of political and cultural issues, such as the social implications of developments in biomedical science, and the political consequences of terrorism.

From a linguistic perspective, Habermas's main accomplishment was his attempt to put insights gained from the study of everyday linguistic practice at the heart of a theory of rational action and of society at large. Drawing on the work of Bühler, Austin, and Searle, he used a typology of speech acts to characterize the kind of rationality which underlies communicative action, and which he viewed as a potential for emancipation. He started from a distinction between success-oriented action and consent-oriented action. The former is exemplified both by

instrumental actions using nomological knowledge of nature, and by strategic actions aimed at achieving coordination between rational agents. By contrast, consent-oriented action consists of a cooperative attempt to reach agreement about the interpretation of the situation that confronts the participants in communication, and about the best plans for action in that situation. When individuals engage in this kind of communicative action, there are three types of speech acts involved: constative, regulative, and expressive speech acts. Every speech act, regardless of type, is related to three sorts of validity claims, which can be accepted or rejected by the hearer. Thus, the hearer can reject a speech act for not being right with respect to norms (for example, an order can be unacceptable in a certain context), for not being truthful (when there is doubt about the intentions of the speaker), or for not being acceptable with respect to truth (for example, when the speaker assumes certain conditions to be fulfilled which in fact are not) (*Theorie des kommunikativen Handelns*, Habermas, 1981, I: 369–452).

Halliday, Michael Alexander Kirkwood

M Cummings, York University, Toronto, Canada

© 2006 Elsevier Ltd. All rights reserved.

M. A. K. Halliday was born in Leeds, UK. His father was Wilfrid J. Halliday, a teacher of English and Latin at Pudsey Grammar School and co-editor of the northern counties volume of the *Survey of English dialects* (1962). He was educated at Rugby School (1938–1942), then studied Chinese, as part of his military service, at the School of Oriental and African Studies (SOAS), University of London (1942–1943). After enlisting with the British Army in 1944, he worked with Military Intelligence in India, then returned to SOAS in 1945 as an instructor in Chinese in the military service courses. In 1947 he enrolled in the University of Peking and also taught English there; in 1948 he took his external London B.A. in Chinese. His postgraduate work for the University of London started at Peking University and continued at Lingnan University (Canton). But after his return to London in 1950, he transferred to Cambridge University, where he undertook a dissertation on the 14th-century Mandarin ‘Secret History of the Mongols’ under the supervision of J. R. Firth of the University of London. He became Assistant Lecturer in the Department of Chinese at Cambridge (1954) and received his Ph.D. in 1955. In 1958 he gave up his Cambridge position to take the post of Lecturer in the Department of English Language and General Linguistics, University of Edinburgh, and became Reader there in 1960. This period saw the development of his ‘scale-and-category grammar,’ whose principles are set out in his 1961 publication. In 1963 he moved to University College, London, as Director of the Communication Research Centre. There he was subsequently appointed Professor and founding Chair of the Department of General Linguistics (1965) and Director of the Nuffield/Schools Council Programme in Linguistics and English Teaching (1964–1970). In the latter period, the scale-and-category grammar gave way to its successor, ‘systemic-functional grammar.’ Halliday resigned his chair in 1971, and until 1975 undertook temporary positions at various universities (Brown, Nairobi, Illinois, Essex) and at the Center for Advanced Study in the Behavioral Sciences (Stanford). In 1976 he took up the position of Professor and founding Chair in the Department of Linguistics at the University of Sydney, NSW, where he remained until retirement in 1988. Subsequently he has held temporary positions at universities in Singapore, China, Japan, and the UK. He has received honorary degrees from universities in Australia, Canada,

China, France, Great Britain, Greece, and India. He continues to reside in the Sydney area.

The scale-and-category grammar had its origins in the work of J. R. Firth, particularly his ‘system-structure’ theory. Halliday’s scale-and-category model had a division of language into three strata: the intermediate level of grammar and lexis (together, ‘form’); the upper level of context, which relates form to the situations of its use; and the lower level of substance in which language is encoded as sounds or written symbols. The grammar has four primary categories: unit, structure, class, and system. The units of inclusiveness—sentence, clause, group, word, and morpheme—are arranged on a scale of rank, on the principle that each higher unit includes one or more instances of the next lower unit. Each unit has its own distinctive structure potential, consisting of an inventory of structural elements. Each structural element is realized by a unit at the next lower rank, unless a ‘rank shift’ occurs: when the element consists of some unit at the same rank as, or higher rank than, its own unit. Particular units are also classified on the basis of their syntax (distribution in the next higher unit) and morphology (their distinctive structure potential). Classes and sub-classes are arranged on a scale of delicacy, from the most general classes to the most specific. System represents the paradigmatic relationship within sets of features at increasing degrees of delicacy. The scale of exponence arranges structural elements and the units they consist of successively in top-to-bottom description.

Systemic-functional grammar is a natural development of scale-and-category grammar. Whereas in scale-and-category system is one of four primary categories, in the later development it is the sole primary category. System represents paradigmatic choice at all levels and at all ranks. Choice in one system may imply a further systematic choice of terms; the logical dependency of one system on another is a network, which in principle is elaborated synoptically to comprise in a single network all paradigmatic choices at each stratum of a single language. The relation between the paradigmatic and the syntagmatic components of the grammar is handled by realization rules, which take as input combinations of choices within the network and produce strings of structural elements as output within units at whatever rank.

Function in systemic-functional grammar is understood in two senses. The primary or ‘meta’-functions divide the general meaning of discourse into three parts: ideational meaning, itself split into experiential meaning (i.e., propositional) and logical meaning, then interpersonal, and finally textual. These functional divisions permeate the grammar from top

to bottom. Any whole utterance or any single form may have propositional content and logical structuring and also implications for social intercourse, and at the same time possess important text-forming features. The second meaning of function is as a term for the elements of structure within units, e.g., subject within clause, or modifier within group.

Systemic-functional grammar has been extended into a number of other important language-related disciplines, such as clinical research and practice, discourse studies, educational theory, and natural language computation. Within the latter it has led to the development of the Nigel grammar component of the Penman text generation system.

Hill, Jane

S O'Neill, University of Oklahoma, Norman, OK, USA

© 2006 Elsevier Ltd. All rights reserved.

Jane Hassler Hill was born in Berkeley, California on October 27, 1939. After taking her first course in linguistic anthropology at Reed College, Hill's fate as a scholar was sealed. Stirring a lifelong passion for language, Hill later continued her studies at UC Berkeley, where she completed a B.A. in anthropology in 1960, winning the prestigious departmental prize on graduation. For her graduate training, Hill traveled to UCLA, where she studied with William Bright and Harry Hoijer, two respected linguists in the Americanist tradition. There she completed an M.A. in linguistics in 1962, followed by a Ph.D. in anthropology in 1966. Hill is best known for her cutting-edge research in linguistic anthropology, encompassing everything from language contact and prehistory to worldview, racism, and language obsolescence. Hill is also a respected descriptive linguist.

Over the course of her career, Hill has contributed widely to Uto-Aztecan linguistics, starting with her dissertation on the Cupeño language of southern

California. Following in the tradition pioneered by Franz Boas and Edward Sapir (see Sapir, Edward), Hill's work with several elderly Cupeño speakers led to the first definitive grammar of this virtually undocumented language, a study she followed with a series of articles on stress, lexicalization, clause structure, and verb classes. Decades before, one of Alfred Louis Kroeber's students, Paul-Louis Fay, had conducted preliminary fieldwork on Cupeño, allowing Hill to compare Fay's notes with her own, and leading to a lifelong interest in language obsolescence. Hill has also published on issues of prehistory, contact, honorifics, and color terminology in the Uto-Aztecan language family.

Hill's longstanding interest in contact and attrition culminated with the publication of *Speaking Mexicano* in 1986, a work she coauthored with her husband, Kenneth Hill. Set in the Malinche Volcano region of central Mexico, among Mexicano speakers, a language that descends from classical Nahuatl, the book focuses on the structural effects of contact with Spanish. Over the centuries, Mexicano absorbed a number of features from Spanish, including nouns, verb roots, grammatical affixes, and syntactic templates. Though many Mexicano speakers

are bilingual, the community as a whole has opted not to shift to Spanish across-the-board, owing to a pervasive ideology that attributes distance to Spanish and intimacy to Mexicano. Instead, the speakers of Mexicano have collapsed the opposition between the two languages in many settings, a situation that Hill and Hill describe as 'syncretism' rather than mere mixing. Once juxtaposed, speakers can either highlight or suppress the ideological overtones of the two speech forms, claiming the power, for instance, associated with Spanish or, alternatively, creating a subtle parody of the Spanish-speaking world. Ironically, a new ideology of purism, which places a strong preference on classical Nahuatl, now threatens what survives of the language today, with its strong Spanish influence.

Jane Hill has earned a reputation as one of the most distinguished scholars currently working in the tradition of linguistic anthropology. After a stint at Wayne State University, Hill accepted a position at the University of Arizona in 1983, where she currently holds the title of Regent's Professor. Hill also served a term as President of the American Anthropological Association in 1998–1999. In 2004, Hill was awarded the prestigious Viking Fund Medal, in recognition of her outstanding record of service and scholarly research in linguistic anthropology.

Historical Pragmatics

A H Jucker, University of Zurich, Zurich, Switzerland

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Historical pragmatics is a field of study that lies at the intersection of historical linguistics and pragmatics. It has established itself as an active field of inquiry since

the mid-1990s as a result of a broadening of both historical linguistics, which started to replace a view of language as a coherent and homogeneous system by a more corpus-driven approach, focusing on genre-specific conventions and the internal variability of older stages of language, and a simultaneous broadening of pragmatics, which started to accept an increasingly wide range of data, including also

written data. As a consequence, historical pragmatics defines itself as the study of pragmatic aspects in the history of specific languages. The field is also called historical discourse analysis or historical dialogue analysis (e.g., Brinton, 2001; Jucker *et al.*, 1999). The choice of terms may sometimes imply a specific perspective, but often they are used interchangeably.

Data

Spoken interaction from the past is not directly available for inspection, but this is no longer seen as problematic for historical pragmatics for several reasons. Instances of recorded spoken language abound in historical data. Court records, for example, contain verbatim accounts of the words spoken during the course of legal proceedings in a law court. Plays consist almost entirely of fictional accounts of spoken language. Early scientific textbooks are often written in the form of fictional interactions between a master and a student. Narrative fiction may contain long stretches of reported discourse. And language teaching textbooks often provide model conversations, e.g., for the merchant traveling to a foreign country.

In all instances, the reliability of these data is an issue. Court proceedings were presumably formal and thus not typical of everyday language. Prescriptive models in language textbooks and representations of conversations in drama or fictional narratives cannot be taken as accurate renderings of the spoken language of any particular period. Therefore, on the one hand, these historical records of spoken language may give us an approximation of the real spoken language in different historical and sociocultural contexts; on the other hand, these instances warrant a pragmatic analysis in their own right. Thus, we may analyze the use of discourse markers in a play by Shakespeare, not because we believe that this is a particularly good approximation to how discourse markers were used in spoken conversations of Shakespeare's time, but because we are directly interested in how Shakespeare used discourse markers in his plays. (*see Discourse Markers*).

In addition, Koch and Oesterreicher (1985), in a widely adopted model, have argued for a need to distinguish between the realization of language in a particular medium, and the way language is realized on a scale ranging from the language of immediacy to the language of distance. As to the first, language may be realized either in the phonic code or in the graphic code. But this dichotomy has to be distinguished from the scale formed between instances of the language

of immediacy, which is more typically (but not exclusively) realized in the phonic code, and the language of distance, which is more typically (but not exclusively) realized in the written code. While no historical language realized in the phonic code is still available, there is sufficient data on the language of immediacy, as for instance in diaries or in personal correspondence.

Moreover, even written texts that lack any connection to the spoken language and that are manifestations of the language of distance are always produced in a communicative context by writers who want to communicate with their readers, and as communicative events they are amenable to pragmatic analyses.

Topics in Historical Pragmatics

Several distinct subfields of historical pragmatics can be distinguished. The first approach, which has been called 'pragmaphilology' by Jacobs and Jucker (1995), studies pragmatic aspects of historical texts in their sociocultural context of communication. Such studies are not new, except for their more explicit reliance on recently developed descriptive tools from the fields of pragmatics and discourse analysis. These may range from ethnographic descriptions of communicative events to the various forms of politeness attested in historical data and to discourse analytical investigations. They also include an approach that may be termed 'literary historical pragmatics.' Fitzmaurice (2002), for instance, provides a pragmatic reading of familiar letters in 17th- and 18th-century England which takes into account intended and unintended meanings implied and inferred by writer and audience. Sell (2000) deals with literary texts of the past. He argues that literary activity should be seen as communication in a strongly interactive sense, as it is affected by the different situationalities of sender and receiver. In the case of literature, sender and receiver are often separated not only in place but also in time. In this case, the literary critic, or the historical pragmaticist, has the task of mediating between the situationalities.

The second approach, diachronic pragmatics, studies the historical development of pragmatic elements, such as discourse markers or speech acts, or it studies the pragmatic causes of language change. To the extent that different stages in the history of a language are compared, historical pragmatics is a kind of contrastive analysis. As in any contrastive study, it is important to specify the *tertium comparationis*, i.e., the element that remains constant when different diachronic stages are compared. It has become standard to distinguish between 'diachronic form-to-function mapping' and 'diachronic function-to-form mapping'

(see Jacobs and Jucker, 1995: 13). An example of the former are discourse markers or pragmatic markers, which are typically marginal forms with little or no propositional meaning that occur outside the syntactic structure and which function on the interactional or pragmatic level. Brinton (1996) examines a variety of such markers in Old English and in Middle English. In this case, linguistic forms that stay relatively stable are taken as a starting point, and their different functions at different stages of their diachronic development are traced.

If, on the other hand, a linguistic function, such as the expression of politeness, is taken as starting point, the term *diachronic function-to-form mapping* is used. In this case, the different realizations of this function in the course of time are studied. Arnovick (1999), for instance, traces the histories of a number of speech acts, such as promises, curses, blessings, greetings, and entire speech events, such as flying and sounding, which she collectively calls *illocutionary biographies*. Jucker and Taavitsainen (2000) argue that histories of individual speech acts have to be situated within a multidimensional pragmatic space in which the speech act can be contrasted with neighboring speech acts.

Often, however, the distinction between these two perspectives is not easy, because in the course of time a particular linguistic element may change both its form and its function. And in some cases the object of investigation is not a particular form or a particular function but a more comprehensive system of interconnected entities, as in the case of address term systems (see Taavitsainen and Jucker, 2003). Many languages distinguish between a more polite and a more intimate personal pronoun of address, such as French *vous* and *tu* or Early Modern English *you* and *thou*. Some languages have more than just two such pronouns of address (e.g., German at some stage of its development, see Listen, 1999). Such systems undergo multivariied developments at different levels. Busse (2002) investigates the morpho-syntactic variability of the second person pronouns in the plays by William Shakespeare and seeks to identify the factors that influence the choice of *you* versus *thou* and *ye* versus *you*.

The cover term *diachronic pragmatics* is also used for approaches that study the pragmatic causes of language change. Traugott and Dasher (2002), for instance, argue on the basis of extensive corpus data from English and Japanese that there are predictable paths of semantic change because such changes are pragmatically motivated, that is to say they are bound up with mechanisms called *invited inferencing* and *subjectification*.

Recent Advances

To date, a disproportionate amount of research in historical pragmatics is devoted to the history of English, but important work has been carried out in several other and less-well researched languages. Xing (2004), for instance, investigates the pragmatic factors affecting the development of a specific focus particle in Mandarin Chinese. Lunde (2004) examines reporting strategies in medieval East Slavic hagiography and homiletics, and Collins's (2001) study is devoted to the distribution of reporting strategies in a corpus of medieval Russian texts.

The papers published by Bax (2003) testify to the importance of rituals in language change in diverse language situations, ranging from ancient Indo-European religious poetry (Vedic hymns) to ritual politeness in early modern Dutch letter writing and ritual aspects of contemporary mass sports events. The language of the mass media has also received increasing attention from historical pragmaticists, for instance in the papers published by Ungerer (2000) and by Herring (2003), which provide an historical view on mass media communication, and thus show that historical pragmatic analyses can also be applied to changes in progress.

History of Pragmatics

B Nerlich, University of Nottingham, Nottingham, UK

© 2006 Elsevier Ltd. All rights reserved.

Pragmatics, the study of sign use and sign users in situations, is usually considered to be a fairly recent addition to the language sciences (see **Pragmatics: Overview**). The term *pragmatics* is generally said to date back to the work of the American semiotician and behaviorist Charles Morris and his distinction of the three parts of semiotics: *syntactics*, *semantics*, and *pragmatics*. The foundations for pragmatics as a linguistic discipline are regarded as having been laid by ordinary language philosophers and speech-act theorists such as Ludwig Wittgenstein, John L. Austin, John R. Searle, and H. Paul Grice (see **Austin, John L., Grice, Herbert Paul, Wittgenstein, Ludwig Josef Johann**).

By adopting this new approach to language, studied as a kind of human action, philosophers and

linguists hoped to overcome an overly narrow study of language as a closed system to be analyzed in itself and for itself, as advocated in structuralist traditions of linguistics after Ferdinand de Saussure and Noam Chomsky. Since the 1970s, pragmatics has become the focus of interest not only in mainstream linguistics, but also in communication studies, discourse analysis (including applied studies in the schoolroom or courtroom), conversation analysis, in psychology, the social sciences, artificial intelligence, and in the study of language and cognition. The study of language has therefore gradually widened its scope during the last half of the 20th century, from the *sign* to the use of signs in social situations, and from the *sentence* to the use of utterances in context.

Half a century after widening the scope of linguistics in this way, it has, however, become clear that a wider pragmatic perspective on language, social interaction, and mind had, in fact, already existed

well before Austin made it popular in the 20th century (Nerlich and Clarke, 1996, 2000, where more references can be found) (see **Pragmatic Acts**).

This history of pragmatics will concentrate on uncovering the roots of the *different approaches to pragmatics* that one can distinguish in Europe and America: (1) the Anglo-Saxon approach which emerged from *ordinary language philosophy* with Wittgenstein, Austin, and Searle, and which has dominated the field, and which (2) developed concurrently with, but independent of, the school of *British contextualism and functionalism*; (3) the French approach, which is based on the *theory of enunciation* elaborated by Émile Benveniste; (4) the German approach (associated with the *critical theory movement* around Jürgen Habermas and Karl Otto Apel), which wants to study pragmatics as part of a general theory of (communicative) action (see **Habermas, Jürgen**).

These European traditions of pragmatic thinking were affiliated in various ways with the development of *pragmatism* as a new philosophy that emerged in the United States in the latter part of the 19th century, and which made the three-way split between syntactics, semantics, and pragmatics popular in linguistics, philosophy, and semiotics.

All approaches, the two Anglo-Saxon ones, the French one, the German one, and the American one, have their deeper roots in Antiquity, that is, in *rhetoric*. They are also all based, to various degrees, on Immanuel Kant's philosophy of the 'active (transcendental) subject' and on John Locke's philosophy of the 'semiotic act.'

These pragmatic modes of thought can be studied as *historical traditions*, but they can also be analyzed as *theoretical frameworks* that cluster around certain pragmatic key words:

1. Anglo-Saxon: speech act, meaning, use; meaning, intention, context, function
2. German: agenthood of (transcendental) subject, dialogue, pronouns
3. French: subjectivity, markers of subjectivity, indexicals
4. American: meaning as action, the triadic sign relation.

These four traditions should not be regarded as monolithic, unchanging, and exclusive. Since the 1970s, many approaches have developed that deal with language in use, such as, to mention just a few, the social pragmatics developed by Jacob Mey (Mey, 2001), also called *language in use* theory, the systemic-functional approach to language developed by Michael A. K. Halliday (Halliday, 1978) (see **Halliday, Michael Alexander Kirkwood**), the various types of (critical) discourse analysis (see Mey, 1979,

1985; Beaugrande, 1996), and more recently the pragmatic and critical approach to metaphor analysis one could call the theory of *metaphor in use*.

Sources of Antagonism and Inspiration

It is generally assumed that language was studied as an *organism* in the 19th century and as a *system* in the 20th. This does not seem to leave much room for the study of language in use or in context or the study of the relationship between language and action. However, looking at disciplines adjacent to linguistics, such as various kinds of philosophy, psychology, sociology, and semiotics, one can discover that the roots of pragmatic thinking go back as far as the 19th and early 20th centuries. Inasmuch as these disciplines influenced the fringes of official linguistics, they also triggered pragmatic insights in linguistic thinking itself, especially in its reflection on meaning.

Those linguists who were interested in the meaning and use of language and not only, like the majority of their historical-comparative colleagues, in sound change, turned to an older source of pragmatic inspiration: rhetoric. Since antiquity, and since the Middle Ages as part of the trivium (rhetoric, grammar, logic), rhetoric had been part and parcel of language studies. However, in their efforts to constitute linguistics as an autonomous science, historical-comparative linguists had focused almost exclusively on the study of grammar, detaching it from the study of language in discourse (rhetoric) and from logic. By contrast, in their study of meaning and discourse, linguists and philosophers not working in the mainstream of historical-comparative linguistics made use of some of the concepts inherited from rhetoric (as for example the figures of speech, the situation of discourse, the interaction between speaker and hearer, and the tripartition of grammar, logic, and rhetoric itself, which is at the root of many semiotic triads).

Among those who redefined and criticized the use of the concept of organism as a metaphor for the study of language, many also rejected an older philosophical theorem, namely that language represents thought (or ideas) and that only language that represents thoughts or the world is worthy of philosophical inquiry, as Aristotle had claimed in *De Interpretatione*, 17a, 1–5 (see Whitaker, 1996).

For pragmatic thinkers of all times, by contrast, language is not only there to represent true or false states of affairs, but it is used to influence others in specific ways, to communicate with others, to act upon others, and to make them act in certain ways, in other words, to change the world. This is why Austin later rejected the philosophy of language developed by those logical positivists who paid lip

service to pragmatics, but still only studied statements as mapping onto states of affairs and the understanding of statements as the understanding of truth conditions. For some of the early pragmaticians, as well as for the later ones, language was also not simply a system of conventional signs for the representation of thoughts. They reflected instead on the motivation underlying the signs' sound-structure and meaning, on the 'naturalness' of language, as one would say now, and on the sources of that motivation in the speakers and the speech situation, in the uses they make of signs in situations.

Early Pragmatic Insights

In Germany, the representational theory of language was undermined in the tradition of Kant, whose theory of the active organizing powers of the mind gave the impetus for a philosophy of language based on the mental acts of the speaker/hearer, especially in the works of Johann Severin Vater, August Ferdinand Bernhardt, and Wilhelm von Humboldt, published during the first two decades of the 19th century. These thinkers gradually replaced the philosophical study of the subject-object relation by a linguistic study of the subject-subject relation, and, in doing so, they developed a dialogical approach to language. The following quote from Vater's work, in which he develops a pragmatic conception of the sign (influenced by Locke's semiotics and Johann Heinrich Lambert's philosophy of language), will demonstrate this tradition, which ends with Humboldt's study of dialogue (for more information on the Kantian tradition, see Perconti (1999).

One can define these concepts [the sign, etc.] from the following points of view: (1) the one who signifies, (2) the one for whom one signifies, (3) the purpose of the signification, (4) the success, the reciprocation of this purpose, (5) the sign, as the means, and (6) that which is signified (Vater, 1801: 137; all translations are Nerlich's).

Compare with Humboldt:

It is particularly relevant to language that duality has a much more important role in it than anywhere else. All speech is based on interlocution (*Wechselrede*), in which the speaker always posits the addressee as the one person opposite him, even when there are more people around. [...] To divide humanity into two classes, the natives and the enemies, is the basis of all primitive social bonding (Humboldt, 1963 [1827]: 137–138).

During the second half of the 19th century, the German pragmatic tradition focused even more on the role of the hearer and on language understanding in situation, possibly under the influence of the

hermeneutical tradition (from Friedrich Schleiermacher to Wilhelm Dilthey).

In England, the representational theory of language was overthrown in the writings of the Scottish school of common sense philosophy, in particular the work of Thomas Reid. Reid remarked that Aristotle had been right to observe that

besides that kind of speech called a *proposition*, which is always either true or false, there are other kinds which are neither true nor false, such as a prayer or a wish; to which we may add, a question, a command, a promise, a contract, and many others (Reid, 1872, vol. II: 692).

However, according to Reid, Aristotle had been wrong in relegating the study of these speech acts other than the proposition to rhetoric (or to the domain of what is now called the pragmatic 'wastebasket' (see Mey, 2001: 12–15):

The expression of a question, of a command, or of a promise, is as capable of being analyzed as a proposition is; but we do not find that this has been attempted; we have not so much as given them a name different from the operations which they express (Reid, 1872, vol. I: 245).

Reid therefore developed a philosophical theory of meaning and a theory of speech acts that could accommodate these types of sentences. He stressed that, unlike statements, these other sentences are fundamentally 'social operations,' because their success necessarily depends on their uptake by others. Reid's views on language spread widely, from Scotland to England, mainly Cambridge, to the United States, and to France.

Whereas Reid had mainly focused on speech acts as social acts and thus contributed to speech-act theory *avant la lettre*, the philosopher and elocution teacher Benjamin Humphrey Smart developed a contextualist theory of meaning as his contribution to a general theory of signs and to early pragmatics. In his *Outline of sematology: or an essay towards establishing a new theory of grammar, logic, and rhetoric* (Smart, 1831), Smart took up Locke's threefold division of knowledge into (1) *physiology*, or the study of nature, (2) *practology*, or the study of human action, and (3) *sematology*, the study of the use of signs for our knowledge, or, in short, the doctrine of signs (Smart, 1831: 1–2). His study deals with signs "which the mind invents and uses to carry on a train of reasoning independently of actual existences" (Smart, 1831: 2). For Smart, sematology (as later semiotics for Morris, and going back to the medieval trivium) had three parts: grammar, logic, and rhetoric. In all three parts, Smart makes it clear that signs do not *mean* ideas, they are *used* to mean something in *context*.

He quotes the following passage from the work of the Scottish common sense philosopher Dugald Stewart, a follower of Reid:

our words, when examined separately, are often as completely insignificant as the letters of which they are composed; deriving their meaning solely from the connection, or relation, in which they stand to others (Stewart, 1854–1860, V: 154–155).

Smart was widely read, although it seems more by thinkers working outside linguistics proper, such as Charles Darwin. The term Smart used for his philosophy of language in context, *sematology*, was later used idiosyncratically by the German psychologist Karl Bühler, but Smart's theory of signs as part of his epistemology was also continued, to some extent, by those working in the tradition of 'significs' (see more on significs below).

Locke and the opposition to Locke were also important in France. Etienne Bonnot de Condillac and the Ideologues had based their philosophy of language in part on Locke's representationalism and empiricism, and saw in language a system of signs for the representation of ideas and sensations. After the French Revolution, in which the Ideologues had been involved, and during the French Restoration, their sensualist (and therefore quasi-materialist) philosophy of language was attacked by French philosophers and psychologists of the eclectic school, such as Victor Cousin, Théodore Jouffroy, and also Maine de Biran, who drew on ideas taken from Kant's philosophy of the active spirit, as well as from the common sense philosophers in Scotland and England, such as Reid. Based on their theories and Reid's conception of social acts, Adolphe Garnier formulated, about 1850, a theory of speech acts (orders and promises, for example) which highlighted the social aspects of speech acts, that is, both the interaction between (the intention of) the speaker and (the understanding by) the hearer, and the interlocutors' social position in the context of discourse. However, Garnier's speech-act theory went almost unnoticed. It was only at the beginning of the 20th century that the legal philosopher Adolf Reinach formulated a similar, but much more elaborate, theory of speech acts, or what Reinach called, with Reid, *social acts*, based, in part, on Edmund Husserl's phenomenology. For Reinach, speech acts, such as commands, can only exist *qua* command insofar as they are not divided up into a statement or *constatation* and its performance. They are both part of *the social act* (Reinach, 1913: 708; Engl. transl. 1983: 20), similar to what Jacob Mey (Mey, 2001: 206–235) later called *pragmatic acts* (see **Speech Acts; Pragmatic Acts**).

The Development of Pragmatics between 1850 and 1930

Gradually, Cousin's philosophy was replaced in France by Hippolyte Taine's rationalist and positivistic psychology. In Germany, too, psychology, especially Friedrich Herbart's mathematical psychology, became more important than philosophy for the advancement of the study of the nature of language. Herbart himself proposed that language could only be understood in the context of human action in general; a view repeated (without direct reference to Herbart, but totally in his spirit) by William Dwight Whitney in the United States (who also stressed the social dimension of language as an institution), by Johan Nicolai Madvig in Denmark (who stressed the role of context and developed a theory of meaning as use), and by Philipp Wegener in Germany who studied not only language in context but also what he called the *dialogic speech-act*, and what H. P. Grice was later to call *conversational implicatures* (see **Implicature, Grice, Herbert Paul**). Wegener analyzed, for example, (elliptical) 'statements' that function as commands:

In the word-sentence 'my boots', the pure word-image does not trigger the representation of the facts that (1) somebody orders an action; (2) what that action is; (3) who should execute the action. All this can only be inferred from the situation and the gestures. The word-image only evokes the representation of a definite thing that the speaker has in mind as an object (Wegener, 1921: 9–10).

Heymann Steinthal, another follower of Humboldt and Herbart, and one of the most famous psychologists of language in the 19th century (read and criticized by Madvig, Whitney, Wegener, and many others), did not directly contribute to a pragmatic theory of language, but, inspired by Steinthal's work and the Russian linguist Aleksandr A. Potebnya, developed an original theory of language and meaning based on the concept of psychological activity. (For the Russian tradition, especially Voloshinov and Bakhtin, see Nerlich (2000). See also Voloshinov, Valentin Nikolaevich; Bakhtin, Mikhail Mikhailovich.)

In France, Taine's call *back to Condillac*, and his semiotic theory of signs, was heard by the linguist Michel Bréal who abhorred the widely used metaphor according to which words or meanings 'live and die' like biological organisms. Instead, he argued that

Our forefathers of the school of Condillac, those ideologists who for 50 years served as target to a certain school of criticism, were less far from the truth when they said, in simple and honest fashion, that words are signs. [...] *Words are signs*: they have no more existence

than the signals of the semaphore, or than the dots and dashes of Morse's telegraphy (Bréal, 1964 [1900]: 249, italics ours).

However, Bréal did not only study language as a system of signs, but also as the expression of the speaking subject, who uses language to express emotions, beliefs, wishes, and demands, that is, to accomplish speech acts. He also analyzed the traces left in speech of the speaker using language, as for example the function of markers such as *nevertheless*, *hopefully*, etc. Furthermore, like Reid and others, Bréal criticized what Austin later called the *descriptive fallacy* in linguistic thinking. Compare:

Language is not only made to say: 'the sun shines on the countryside', 'the rivers flow into the sea'. Beyond that, language serves mainly to give expression to desires, demands, to be the expression of the will. It is this *subjective* side of language that should be studied more [...] (Bréal, 1877: 361–362).

The topic of the subjectivity in language was taken up by the French counterpart to Anglo-Saxon speech-act theory, viz., the theory of enunciation, as elaborated by Charles Bally, Gustave Guillaume, and Émile Benveniste (see **Bühler, Karl**) and amalgamated with a theory of speech acts in the work of Oscar Ducrot. These French linguists also studied what they called the actualization of language (*la langue*) in speech (*la parole*) through what Roman Jakobson, for example, called *shifters*, and Bally called *indicators*.

But Bréal not only initiated a study of subjectivity and indexicality in language, but also promoted a functionalist approach to language. Quite early on in his career, while actually introducing German historical-comparative linguistics to France, Bréal began to criticize its organicism and its way of studying linguistic forms without taking into account their function. For Bréal, as for other 'functionalists' of that time (such as Wegener), function was the primary force of language change. Forms do not change in sound or meaning all by themselves, but because they are used with a specific function by the language user in discourse and in a certain situation. Other French functionalists were the psychologists Frédéric Paulhan and Henri Delacroix, and the linguist and medical doctor Eugène Bernard Leroy. Paulhan, in particular, established an explicit theory of speech acts in the context of a theory of linguistic functions that is directly comparable to that developed by Karl Bühler in Germany (more on Bühler below). Using an example that has become commonplace in pragmatic writing, he points out that:

[I]n order to understand the words 'it's raining', it suffices that, consciously or half-consciously, I take my

umbrella with me when I want to go out. If I act in this way, I can really say that I have understood the words 'it's raining', even though I might not have associated them with any images that they represent (Paulhan, 1886: 47).

The German functionalists and speech-act theorists *avant la lettre* at the turn of the 19th to the 20th century, especially Anton Marty and Bühler, were influenced by rationalist linguists such as Whitney, Madvig, Wegener, and Bréal on the one hand, but also, on the other, by new developments in psychology, such as the descriptive psychology developed by Franz Brentano, by the psychology of Gestalt, by phenomenological psychology, as well as by developments in social behaviorism.

Bühler (who was also a great admirer of Wegener) was working in the context of the Würzburg school of psychology, and he knew the work of Marty and Edmund Husserl well. He established the most elaborate theory of pragmatics in Germany (Bühler, 1934), of which his 'organon model' was the central part. In this model, he places the linguistic sign in its context of use, bringing into the model the speaker and hearer (forgotten in the semiotic triangle popularized by Charles K. Ogden and Ivor A. Richards) and the reference to 'things' (forgotten in Ferdinand de Saussure's famous speech circuit). The organon model, depicted by a triangle overlaid upon a circle, shows that every sign is at one and the same time a symptom (indicator, index) by virtue of its dependence on the sender (whose internal state it expresses), a signal by virtue of its appeal to the recipient (whose behavior it controls), and a symbol by virtue of its assignment to the objects and states of affairs (to which it refers). And so, every sentence is at one and the same time *expression*, *appeal*, and *representation*. These are also the three main functions of language and sign use.

This functional and semiotic theory of language was further elaborated by linguists, such as Erwin Koschmieder and Alfons Nehring, as well as by philosophers, such as Karl-Otto Apel and Jürgen Habermas (see **Habermas, Jürgen**). Koschmieder, also influenced by Husserl, developed one of the first theories of performatives in Germany, a theory which can be directly compared to that which was being developed on the other side of the English Channel by Austin.

As early as 1929, Koschmieder had hinted at some puzzling syntactic phenomena of tense and aspect which would lead him to postulate a new "case of coincidence" (Koschmieder, 1965 [1945]: 26–27). He discussed the Hebrew equivalent of the sentence *I hereby bless him*, and pointed out that in such examples the action arises in the very utterance, that is to

say: action and utterance coincide. He also used the example (later made famous through Austin): *Hiermit eröffne ich die Versammlung* ('I hereby open the meeting', i.e., 'I declare the meeting to be opened'), and he pointed out that *Hiermit schreibe ich einen Brief* ('I am hereby writing a letter') is impossible.

A Cambridge psychologist, George Frederick Stout, working toward the end of the 19th century, was also influenced by Brentano, as well as by Herbart and by Kant. From Kant, he took the insight into the active organizing powers of the individual in understanding the world and applied it to the individual using language. Stout was opposed to English associationism as proposed for example by Alexander Bain (Bain, 1855) and John Stuart Mill, and put forward a contextualist theory of language that incorporated some principles reminding one of the later Gestalt school of psychology. He was especially interested in the context-sensitivity of the notions of subject and predicate, thereby implicitly challenging linguistic analysis in terms of logic alone. He thus contributed to the development of ordinary language philosophy in Cambridge.

The psychological work of Paulhan and Stout was appreciated by the English philosopher and philanthropist Lady Victoria Welby, whose work on "meaning" (which she called *significs*) started an English and a Dutch school of pragmatics (named 'significa'), in which not only was context important, but language use and the whole speech event (including the speaker's intention and the hearer's interpretation) were taken into account (see Schmitz, 1990).

The English school of contextualism (Sir Alan Henderson Gardiner, Bronisław Malinowski, John Rupert Firth) was partly based on the work of Welby (just as later also was Ogden and Richards' work, who, too, can be counted among the functionalists) on the one hand, and on the work of Wegener (which was much less metaphysical and more 'pragmatic' than Welby's) on the other. Gardiner wanted to analyze "acts of speech," Firth whole "speech events," and Malinowski wanted to study meaning as action. In his famous supplement (on meaning in primitive languages) to Ogden and Richard's book *The meaning of meaning*, Malinowski claimed that language is "a mode of action," especially of cooperation between people (Malinowski, 1923: 315).

The meaning of meaning also contained an extract of Peirce's work on semiotics as a direct result of Lady Welby's influence. In the early years of the 20th century, Lady Welby had corresponded with the father of pragmatism and semiotics, the American philosopher Charles Sanders Peirce. Peirce had inherited the term *pragmatisch* from Kant (in the latter's distinction between *practical* reason, that is, of the 'pure kind,' and

pragmatic reason, that is, of the 'empirical' kind), and he knew the semiotic literature of the past well, from the Medieval philosopher Peter of Spain to Locke, Reid, and Welby. His counterpart, the pragmatist psychologist William James, by contrast, derived the term *pragmatism* from the Greek *prágma*, meaning 'practice', 'action'. And, whereas Peirce's *pragmaticism* (a term Peirce introduced to set his theory off against James's) became part of his semiotics, as a general theory of signs and of meaning, James's *pragmatism* became part of a morally based psychology and theory of truth (see Peirce, Charles Sanders; Morris, Charles).

Inspired in part by some principles of pragmatism, but also by Ogden and Richards' theory of signs and symbols, as well as by developments in logical positivism and behaviorism, the American Charles Morris is well-known for his tripartition of semiotics into *semantics*, as the study of the relationship between words and the world, *syntactics*, as the study of the relationship between words and words, and *pragmatics*, as the study of the relationship between words and their users (Morris, 1938). He made this the basis for a behavioristic type of semiotics.

The problem of 'meaning,' so important to Lady Welby and the pragmatists, became the focus of philosophical thinking worldwide. This was especially the case in England where, from the turn of the 19th century until the mid-20th century, it was leading up to the 'linguistic' and then 'pragmatic' turns in the philosophy of language. Initially, philosophers, such as the Oxford philosopher and classical scholar Austin, used linguistic analysis to find philosophical clarity; later, linguists used philosophical methods, such as those advocated by Austin, to study wider aspects of language. Here one can trace a line of thought leading from Gottlob Frege to Russell and the early Ludwig Wittgenstein (Wittgenstein I), to the later Wittgenstein (Wittgenstein II), Gilbert P. Ryle, Peter F. Strawson, Austin, H. Paul Grice, and finally to John Searle. Searle had written his Oxford D.Phil. thesis under Austin and Strawson on Frege's notion of sense and reference, and his concept of 'illocutionary force,' so central to pragmatics, can be traced back to Frege.

Pragmatism, Semiotics, and Speech Act Theory

As we have seen, many psychologists, philosophers, and linguists shared what Malinowski once called a "pragmatic *Weltanschauung*" (Malinowski, 1923: 328) at the turn of the 19th into the 20th century. They all regarded language as a mode of action and interaction. This conception was not unknown to Austin, who had read Gardiner, Morris,

Peirce, and others. However, it seems that Austin neither wished to be associated with the contextualist-functional pragmatics developed on his doorstep (Nerlich, 1996), nor with the pragmatist, behaviorist, and semiotic pragmatics developed on the other side of the Atlantic by Morris, nor with the formal type of pragmatics developed by ideal language philosophers such as Rudolf Carnap. Austin also did not accept Morris's tripartition of semiotics into syntactics, semantics, and pragmatics; as he pointed out in 1940:

Now the reason why I cannot say 'the cat is on the mat and I don't believe it' is not that it offends against syntactics in the sense of being in some way "self-contradictory." What prevents me saying it, is rather some semantic convention (implicit, of course), about *the way we use words in situations* (Austin, 1963 [1940]: 10; italics ours).

And,

the supposed "ideal" language . . . is in many ways a most inadequate model of an actual language: its careful separation of syntactics from semantics, its list of explicitly formulated rules and conventions, and its careful delimitation of their spheres of operation – are all misleading. An actual language has few, if any explicit conventions, no sharp limits to the spheres of operation of rules, no rigid separation of what is syntactical and what semantical. (Austin, 1963 [1940]: 13).

It is astonishing to see that Austin does not use the term *pragmatics* in this context, as he implicitly argues for an integration of syntactics and semantics into pragmatics, being the study of the use of words or signs in the situation of a speech act.

Conclusion

Before Austin, the foundations for pragmatics had been laid by thinkers who stressed that:

- Signs are not only used for the expression of thought, but have various other functions.
- Signs have not only an intellectual but also an affective function.
- Sign use has basically three functions: representation, expression, and appeal.
- Signs can only be understood in the context of the situation in which they are used.
- Speaking is a goal-directed action.
- Signs are instruments used in the act of speech, and their use has practical effects and consequences.
- Signs are mainly used to influence others.
- Signs only function in dialogue and conversation; the reciprocity between speaker and hearer is important.

- Signs are used for the coordination of human behavior.
- Some signs are indexically linked to reality and the language users.

Rather late in the development of pragmatics are these ideas:

- Certain speech acts are self-referential.
- In saying something we are doing something.

Humor in Language

N R Norrick, Saarland University, Saarbrücken, Germany

© 2006 Elsevier Ltd. All rights reserved.

There are many spoken and written varieties of humor, from puns to novels, but characteristic techniques recur in all forms of verbal humor, namely production of incongruity based on linguistic constructions or on the events described. Such incongruity can be represented as a clash between opposed semantic scripts. Thus, in the classic one-liner:

A panhandler came up to me today and said he hadn't had a bite in weeks, so I bit him.

The phrase "had a bite" belongs structurally to the build-up, while functioning as the script-switch trigger, that is, the unit around which the joke's dual meaning revolves. The script in force in the build-up, namely a panhandler seeking a handout from a passer-by, vanishes in the punchline, where

a previously backgrounded script takes hold, in which the victimized passer-by becomes the attacker, while the panhandler becomes the victim. Recognition of the sudden script switch releases psychic energy as laughter, according to Freud (1960), Bateson (1953), and others.

In everyday talk we find both spontaneous conversational joking (puns, banter, wordplay), personal anecdotes, and canned jokes (either narrative or non-narrative, as in riddle jokes). Conversational joking can be spontaneous or formulaic. Recurrent conversational situations call for formulaic witticisms like "Born in a barn?" to someone who leaves a door open, and typical joking strategies like hyperbole: "I had about a thousand books to return" and irony: "I love it when it sleets." These utterances generate humor through the speaker's pretense in evoking one script while believing another – often modeled theoretically as a violation of some conversational maxim or the principle of relevance. (see **Maxims and Flouting**.) There are humorous sayings such as, "It's like déjà vu

all over again”; allusions like “Though William shake his spear, Anne hath a way”; proverbial similes like “Colder than a well-digger’s ass”; leave-taking formulas like “See you in the funny papers”; and so on.

A description of the syntax and semantics of jokes as in Raskin (1985) requires to be extended, in order to include a consideration of their interpersonal and social dimensions in real-life contexts (Attardo, 1994, 1997; Attardo and Raskin, 1991). Discourse analysis has begun to elucidate the performance aspects of joke and anecdote telling (Sacks, 1974; Norrick, 2001), and to explore how conversationalists create and respond to humor in interaction, in casual talk among friends (Norrick, 1993) and family members (Everts, 2003), as well as in institutional settings (Holmes, 2000). (see **Critical Discourse Analysis; Institutional Talk.**) We must view joke telling, punning, and teasing in relation to contextualization cues, gender, power, solidarity, and social distance, as well as principles of politeness and cooperation in order to understand how verbal humor can express aggression, yet still build rapport. Joking allows participants to signal their respective affiliations and to align themselves with respect to them. Humor provides a socially acceptable vent for strong emotions toward other people and groups. Some individuals joke with almost everyone; some people kid each other whenever they meet, developing customary joking relationships in which teasing and joking are habitual and competitive. Moreover, conversational humor often revolves around inside jokes – jokes only group members have the shared background knowledge to understand (see **Shared Knowledge; Irony; Politeness**).

Humor: Stylistic Approaches

P Simpson, Queen's University, Belfast,
Northern Ireland

© 2006 Elsevier Ltd. All rights reserved.

Much work in stylistics has demonstrated a sustained and thoroughgoing interest in the connections between patterns of style and aspects of verbal humor. This interest stems in part from stylistics' general concern with text analysis and from its preoccupation with developing analytic models to help explain the ways texts function as discourse. Stylisticians are, however, also interested in humorous discourse as it intersects with the wider study of verbal play and creativity in language. This particular approach is embodied in Nash's seminal study (Nash, 1985), which draws upon a large range of texts, penned by the author himself, to illustrate the full spectrum of types of verbal humor. A further dimension of the stylistic analysis of humor, which works in parallel with the focus on the connections between textual patterns and the humor impulse, is its interest in the differences between humorous discourse and so-called 'ordinary' discourse. The concern here is therefore with exploring how the 'nonroutine' communication that is humorous discourse makes for a useful tool for exploring contrastively the more commonplace patterns of everyday social interaction (Simpson, 1998: 35).

An axiom that underpins most stylistic research on humor runs as follows: for a text to be humorous, it must exhibit (at least) some sort of stylistic **incongruity**. Importantly, the incongruity may operate at any level of language or discourse; that is, at any point on a linguistic continuum that extends from lexicogrammar right up to dialogue and discourse. Puns and related forms of verbal play illustrate well the type of incongruity that is situated at the 'grammatical' end of the continuum. The incongruity in puns occurs when some feature of linguistic structure simultaneously combines two unrelated meanings, thereby allowing a 'double meaning' to be located in what is in effect a chance connection between two elements of language. Lexical puns, for instance, are activated by a clash between polysemous lexical items such as homophones and homonyms, as in Groucho Marx's quip "We only shot two bucks, but that's all the money we had" (see further Simpson, 2003: 16–29).

Situated toward the opposite end of the continuum, some incongruities may be grounded in mismatches between text and discourse context, and this type of humor-inducing strategy has received fullest

explication in stylistic research on drama dialogue. Stylisticians have been especially interested in oppositions between characters' speech strategies and the discourse context (within the play) in which these strategies are framed. Similarly, stylisticians have reached interesting conclusions about the humor mechanism by crossreferencing the way fictional characters interact on the stage with the way they might be expected to interact should they inhabit the 'real' interactive world of playwright and audience/reader. Indeed, this tradition of research has yielded many insightful studies of the Theatre of the Absurd, where rich comparisons can be drawn between the discourse world **inside** the play and the discourse world **outside** the play (see Burton, 1980; Short, 1989; Simpson, 2000; Herman, 1996). By way of illustration, consider the following short scene from N. F. Simpson's absurdist play *One Way Pendulum*, where a courtroom has been hastily assembled inside a domestic living room to facilitate Mr. Groomkirby's 'swearing in' ceremony:

The Usher enters followed by Mr. Groomkirby, whom he directs into the witness box. Mr. Groomkirby takes the oath.

Mr. Groomkirby: (*holding up a copy of Uncle Tom's Cabin*).

I swear, by Harriet Beecher Stowe, that the evidence I shall give shall be the truth, the whole truth, and nothing but the truth.

Judge: You understand, do you, that you are now on oath?

Mr. Groomkirby: I do, m'lord (Simpson, 1960: 60).

Whereas a courtroom is an institutionally designated location that deals exclusively with legal proceedings, it manifestly cannot be set up *ad hoc* in a domestic living room. Moreover, there are established procedures for ritualized activities such as the swearing-in of witnesses, and shared assumptions between participants about the way these routines are conducted form part of the communicative context of a 'real' courtroom. Clearly, the 'swearing in' ceremony here violates the pragmatic preconditions that govern the ritual, and so the communicative competence that organizes everyday interaction for the reader/viewer of the play acts as a frame for interpreting the incongruity of the displayed interaction at the character level on stage.

The principle of incongruity as a humor-inducing technique can be extended, beyond its core sense as a stylistic twist in a pattern of language, to cover situations where there is a mismatch between what someone says and what they mean. This extended pragmatic sense equates roughly with the concept

of irony. Many forms of irony are situated in a discursive opposition between what is asserted and what is meant, as embodied in an utterance such as 'You're a fine friend!' when said to someone who has just let you down. The irony here is located in a departure from Grice's maxim of 'truth' (which dictates that your interactive contribution must be true), although not all irony is explicable within the Gricean model. For example, another conceptual framework, arising from work in Relevance Theory, sees irony as 'echoic mention'; that is, as a type of usage where the utterance echoes other utterances and forms of discourse. This is apparent in an exchange such as the following

A: I'm really fed up with this washing up.

B: *You're fed up!* Who do you think's been doing it all week?

where the proposition about being fed up is used in a 'straight' way by the first speaker, but in an ironic, echoic way by the second (see Sperber and Wilson, 1981).

Irony, in both of the senses identified above, features especially prominently in stylistic research on parody and satire – two forms of verbal humor whose central stylistic incongruities are arguably built upon different kinds of irony. The principle of echoic mention is absolutely central to parody's capacity to function as what Nash terms 'a discourse of allusion' (Nash, 1985: 100). Parody can take any particular anterior text as its model, although more general characteristics of other genres of discourse can also be brought into play. Once echoed, the stimulus text becomes part of a new discourse context so it no longer has the illocutionary force it once had in its original context, and that is what often engenders parody's ironic humor.

Satire has an aggressive element which is not necessarily present in parody. How this translates into stylistic terms is that satirical discourse, as well as having an echoic element, requires a further kind of ironic twist or distortion, of the more 'Gricean kind,' in its textual design. This additional distortion means that while parodies can remain affectionate to their source, satire can never be so. To illustrate, consider this famous passage from Jonathan Swift's satirical pamphlet *A Modest Proposal*:

I shall now therefore humbly propose my own thoughts, which I hope will not be liable to the least objection. I have been assured by a very knowing American of my acquaintance in London, that a young healthy child well nursed is at a year old a most delicious, nourishing, and wholesome food, whether stewed, roasted, baked, or boiled; and I make no doubt that it will equally serve in a fricasee or a ragout (Swift, 1986 [1729]: 2175–2176).

The 'echoic irony' in Swift's text derives from its mimicking of the genre of the early eighteenth century pamphlet, and more narrowly the proliferation of pamphlets offering economic solutions to what was then perceived as the 'Irish problem.' However, the passage also contains an ironic distortion that marks it out as satire. This distortion comes through the startling sequence where the persona proposes to alleviate the burden of overpopulation and starvation in Ireland by eating that country's children. This twist marks an abrupt shift from a framework embodying what is morally acceptable to a framework of abnormality and obscenity.

An important rider needs to be attached to the 'incongruity-based' stylistic work on humor sketched thus far, which is, to put it bluntly, that not all incongruities are funny. Indeed, the type of humor response that a single textual stimulus attracts can vary enormously from recipient to recipient and from context to context. The variability of the humor response has not escaped the attention of stylisticians, and more recent work in stylistic humorology has sought to address both sides, the stimulus and the response side, of the humor event. One model that has come to prominence in this respect is the *General Theory of Verbal Humor* (GTVH) (see Attardo 1997, 2001 for useful compact expositions of the model). A key postulate of the GTVH is that the incongruity element in a humorous text is bounded by a preceding 'setup phase,' which establishes a neutral context for the incongruity, and a 'resolution phase,' which describes the knowledge resources employed by the humor processor to resolve the incongruity. The GTVH thus marks a shift away from an entirely text-centered description of humor toward one that accords equal weight to both textual and cognitive mechanisms of humor processing.

A useful literary-stylistic application of the GTVH is Attardo (2002), which is an exploration of the techniques of verbal humor used in Oscar Wilde's *Lord Arthur Savile's Crime*. Of a number of extensions to the theoretical model, Attardo develops a mechanism for exploring the humor of longer texts—the GTVH traditionally concerns itself with short jokes and quips – part of which involves differentiating between 'punch lines' and 'jab lines.' In multiple joke-bearing texts, the punch line is a humorous instance at the end of a text, while the jab line is a humor instance anywhere else in a text (Attardo, 2002: 235).

Another area where stylistic investigation has sought to move beyond textual description to consider the sociopragmatic features of humor is Simpson's study of satirical discourse (Simpson, 2003). Simpson seeks to isolate the inferencing mechanisms that text

processors need to use in order for a text to become satire. Especially important is the mechanism that allows a text's claim to 'sincerity' to be rescinded – a mechanism that is normally pressed into service on encountering ironic distortions like those sketched earlier. Translated to Swift's satirical text quoted above, the distortion at the textual level results, probably for most readers, in the sincerity condition being rescinded at the pragmatic level, the perlocutionary consequence of which is that the text is read as satire and not as a 'straight' or serious proposal.

Contemporary stylistic approaches to verbal humor will continue to develop models of analysis where descriptions of text are paralleled with descriptions of the text's impact, both social and cognitive, on its readers. One area that is yet to receive adequate scholarly scrutiny is to do with the intersection between humor and other stylistic devices. For instance, while a technique such as literary **foregrounding** relies on an incongruity in its textual design, there remains no adequate account of why some, but not all, foregrounded patterns in a text are funny. The same principal applies to figurative language, where the question again arises as to why, for example, some novel metaphors and metonymies are humorous and some are not. These questions will no doubt be addressed by stylisticians as ever more sophisticated methods of dealing with humorous language present themselves.

Iconicity

J Haiman, Macalester College, St. Paul, MN, USA

© 2006 Elsevier Ltd. All rights reserved.

Iconicity is the idea that a formal property in a sign corresponds through similarity to a property of its referent. The idea was entertained and then rejected by Plato in the *Cratylus*. Plato's conclusion was restated by Saussure as "*l'arbitraire du signe*" and has been a mainstay of all versions of structuralism, including notably generative grammar (cf. Hockett, 1960; Chomsky, 1969). Most standard textbooks dismiss the topic with examples of individual words: *whale* is a small word for a large animal; *micro-organism* is a large word for a small one; QED. The relationship between form and meaning is considerably more interesting than this once we analyze complex signs and sign systems using the notion of diagrammatic iconicity introduced by Peirce (1932), or indeed, Saussure's closely related notion of motivation. A diagram is an attenuated icon if the relationship among its parts in some way approximates the relationship among the elements to which these parts refer. Standard examples of the apparent diagrammatic iconicity of language then include the universal principle of isomorphism, which as a cognitive principle is largely responsible for the operation of grammatical analogy (i.e., "One form should correspond to one concept"). This can be thought of as the iconicity of paradigms. Other standard examples that correspond more to Saussure's motivation include the semantic compositionality of *dix-neuf* and other compounds; Behaghel's first law ("physical closeness corresponds to conceptual closeness"; cf. Bolinger, 1975; Bybee, 1985; Haiman, 1985); several apparently universal ordering principles, such as the order of clauses in a narrative (*I came, I saw, I conquered*; cf. Jakobson, 1965) or in conditional constructions (protasis precedes apodosis; cf. Greenberg, 1966) corresponds to the conceptual or real-time order of the states to which the propositions refer; and the various uses of repetition and reduplication (cf. Moravcsik, 1978), such as XX typically means plurality, distributivity, iterativity, or emphasis

of whatever is denoted by X. This type of motivation can be thought of as the iconicity of syntagms.

It is now widely recognized that systematic correspondences do exist between linguistic diagrams and extralinguistic reality, but the nature of these correspondences is often debated. Following Zipf (1935), it is now acknowledged that a principle of least effort is involved in the creation of linguistic structures, such that familiar, frequently mentioned and unsurprising concepts tend to be given reduced expression. We talk about cars and TV rather than automobiles and television, and there is no language known in which the words for *man* and *woman*—for all the inexhaustible fascination, mystery, and complexity of their referents—are seven-dollar words. It even seems that we consciously control the contrast between fuller and more reduced expressions of the same phonetic strings, depending on whether they are formulaic or novel (Van Lancker and Canter, 1981; Van Lancker, Canter, and Terbeek, 1981), or on whether they are to be interpreted as common nouns or anaphors (Haiman, 2003).

In some cases, the relationship between the reduction (and opacity) of a form and its predictability can be scalar, with different points along a linguistic continuum corresponding with different points along a conceptual continuum, exactly in accordance with an elaboration of Zipf's principle. A striking example is a correlation discovered and defined by Givon (1985) that seems to have considerable cross-linguistic validity: the length and complexity of an anaphoric expression will tend to covary with the remoteness in discourse of its antecedent, all the way from a full noun phrase down to zero. Givon considered this to be an iconic covariation, although the Zipfian motivation for the pattern is apparent.

Challenges to the principle of iconicity today take two forms. The first approach consists in demonstrating that many examples of iconicity in the literature (including possibly all variations on the markedness principle that "more form corresponds to more meaning") can be reduced, like Givon's principle, to economically motivated reductions, the basic principle being to give lesser expression to what is familiar or

predictable. For example, the third-person singular of verbal and nominal paradigms is frequently zero. It could be that this is an icon of the third person as “the absent one” (cf. Benveniste, 1946), but it could be an economically motivated reduction of the most frequently occurring case. Iconicity would then be purely incidental, an epiphenomenal consequence of another drive.

The second approach consists of acknowledging the possible importance of iconicity in primitive signaling between speakers who share no common conventions—perhaps speakers of different languages, perhaps primitive speakers of the first human languages (cf. Grice, 1989: 358, whose insistence that “every artificial or non-iconic system is founded upon an antecedent iconic system” is an expression of this view)—but then emphasizing that through conventionalization iconicity will be very rapidly lost. First come charades and onomatopoeia (indeed, common sense makes us ask what other means there might possibly be at speakers’ disposal), but, once speakers share a common culture, all the conventional features of normal grammar will rapidly appear in their communication, sometimes within a matter of minutes (cf. Bloom, 1979). Although it may seem like no more than common sense that speakers will find it easier to store and process icons than symbols (Givon, 1985), there is little solid evidence that has been adduced in support of this contention. In fact, Benveniste (in linguistics) and Berger and Luckmann (in culture) have recognized that people tend to accept whatever they are familiar with as perfectly natural and to reject all alternatives as alien and barbaric (cf. Anderson, 1990). Motivation, in this view, derives entirely from conventions that are “always already there.” In a way, the argument from convention is related to the argument from least effort because much of the opacity of conventions results from streamlining. But this argument is one that should make the analyst even more skeptical about the possibility of encountering iconicity in any recorded language. If iconicity can be lost within 15 or 20 minutes in a contrived encounter, then what are the chances we will encounter it in languages that have been spoken for any longer than this time? To survive at all, it must be constantly recreated.

To counter such reasonable skepticism, it is necessary to demonstrate that iconicity is an independent and currently productive drive in the genesis of linguistic structures. The constant operation of analogy and the rarity of perfect synonymy may be taken as evidence for the psychological reality of isomorphism or the iconicity of paradigms (“one form corresponds to one meaning”). The iconicity of syntagms is a different matter.

The best evidence for the psychological reality of motivation is the fact that where there are competing structures with roughly the same meaning, speakers will tend to select the form that corresponds to the specific meaning they prefer on the basis of motivation. Stock examples are the contrasts between *hair* (mass noun) and *hair-s* (count noun) or between *kill* and *cause to die* (cf. Wierzbicka, 1980, 1985). But it could be argued that the choice between preexisting structures is not the same as the creation of novel ones and thus provides at best pale evidence for the reality of motivation.

It may seem that the tension between iconic and economic or Zipfian motivation may be a straightforward one that reflects the competition noted by Passy (1890) and von der Gabelentz (1891) between the drive for clarity, on the one hand, and the drive for ease, on the other. Cases such as Givon’s topic accessibility hierarchy and the motivation for the reduced expression of anaphors in general indicate that often the same formal contrasts may have one interpretation here and another one there.

Another example explicitly dealt with by Haiman (1985) is the contrast between light and heavy versions of the reflexive in a number of unrelated languages, including English. Given that there exists a conceptual contrast between introverted actions that people typically perform on themselves (verbs of grooming, dressing, and change of posture) and extraverted actions that they more typically do unto others, the Zipfian principle of economic motivation predicts that the light form of the reflexive is used where the verb is introverted, whereas the heavy form is used where the verb is extraverted. This is borne out in English and in almost all the languages where the light/heavy distinction for reflexives exists:

I shaved.
I kicked myself.

But there is another conceptual contrast that the same morphological distinction expresses. Light reflexives are typically middles or impersonal passives, that is, one-participant activities (cf. Langacker and Munro, 1975; Haiman, 1976). Heavy reflexives never function as impersonal passives because the heavy reflexive morpheme (typically a separate nominal expression) marks a second participant. Thus, the contrast between the next two sentences.

I got up.
I got myself up.

The strong sense of reflexives such as *I got myself up* in English is of a divided or alienated self. In this particular sentence, the subject denotes the will, the

object the flesh. In languages that form their impersonal passives via a reflexive construction, such as Russian, the contrast is:

videt-sja
see-3.SING.REFL
's/he is seen, is visible'

videt sebja
see-3.SING self
's/he sees him/herself' (as in a mirror)

The sense of a divided self is, admittedly, weak in textbook cases of reflexivization involving mirrors (person vs. image of person), but recurs with overwhelming frequency in natural discourse, which is filled with descriptions of people who force themselves to do things they do not want to do, pat themselves on the back, feel proud of or sorry for themselves, hate themselves for their weakness, and so forth (cf. Haiman, 1998: Chap. 5, and the references cited there). Exactly the same formal contrast (light/heavy reflexives) can be iconically or economically motivated.

The light reflexive participates in another contrast, between intransitive and transitive verbs that involve a change of state. In those cases in which the verb root for related transitives and intransitives is the same, there are a number of possible means of expressing the contrast via derivational affixation (see Table 1). Sometimes one language will make the intransitive the basic form, while another language makes the transitive the basic form for the same verb. Thus in English, the verb *bear* (a child) is basically transitive, and the intransitive is the derived passive *be born*. In Turkish, the verb 'be born' is basic *dog-*, and the verb 'bear' is the derived causative *dog-dur-*. But the contrast is not an entirely random one. Zipfian considerations of economy lead us to expect that typically verbs that are generally performed on others will have the bare stem in the transitive and a derived mediopassive in the intransitive, whereas verbs that are conceived of as spontaneous actions will more typically occur in the unmarked form in the intransitive, with a derived causative for the transitive. This is what Haspelmath (1993) found to be the case in a survey of 31 verbs in 21 languages – some complex derived expression (the anticausative) is favored for the intransitives formed from verbs such as *break*,

where it is more probable that an outside force brings about the event. Conversely, actions such as *freeze*, which typically occur without an outside instigator, can be made transitive by the addition of some causative. So, the contrast is exactly parallel to that between introverted and extroverted reflexives, and is a function of purely economic principles: reduced expression is given to the predictable.

The presence of iconicity can most clearly be demonstrated when it comes into conflict with economy and trumps it. Such cases are well known and leave no room for ambiguity. The most striking examples come from the expression of symmetry. Haiman (1985) showed that in Hua (Yagaria), the expression of reciprocity, a symmetrical relationship, cannot be given by a reciprocal pronoun (there are none) nor by straightforward sentential coordination because the structure S1 + S2, as in many Papuan languages, exhibits a morphological asymmetry between the first (medial) and the second (final) clause. The medial verb occurs with two verbal desinences M (medial) and A (anticipatory), which agree with the subject of S1 and S2, respectively, whereas the final verb occurs with a totally distinct F (final) desinence, which agrees with the subject of S2 alone. The morphological asymmetry of the verbal desinences (verb of S1 = V + M + A; verb of S2 = V + F) reinforces the syntactic asymmetry of order, so that a coordinate sentence such as S1 ['Max hit Harry'] S2 ['Harry hit Max'] can mean only something like 'Max hit Harry and thereupon/therefore Harry hit Max'. The problem of reciprocal symmetry is solved in Hua by making the second verb also into a medial verb whose M desinence agrees with the subject of S2 and whose A desinence agrees with the subject of S1. The whole coordinate construction, which models a closed ring, is treated as a nominalization that occurs with a light final verb that agrees with the subject of S1 + the subject of S2.

ebgi-ga-na ebgi-ga-na ha'e
hit-3.SING.M-3.SING.A hit-3.SING.M-3.SING.A
do.3DL.F

'they hit each other'

where DU indicates Dual. There is a more economically motivated way of saying this, which consists of stripping both the medial verbs of their personal desinences and nominalizing the verb stems by affixing the glottal stop:

ebgi-ʔ ebgi-ʔ ha'e
hit-NOM. hit-NOM. do.3.DL
'they hit each other'

The latter does justice to both iconicity and economy, but the first satisfies iconic imperatives alone.

Table 1 Affixation and transitivity

Intransitive	Transitive
Bare stem	Bare stem + causative
Bare stem + reflexive passive	Bare stem

In the same way that we need to distinguish iconic from economic motivation, we have to separate iconically motivated symmetry of this sort from other cases that seem to be motivated by yet other drives. The drive for symmetry without iconic motivation is abundantly attested in a number of Southeast Asian and Oceanic languages. There is an enormous literature on this topic, some of which is summarized in Fox (1988). A particularly striking (if modest) example from English, first noted by Alan Cruttenden, is the phenomenon of radio announcements of tied scores, for example, *Sussex 2, Essex 2*. From the point of view of information structure, both scores are new information and should be read with the same intonation as *Sussex 2, Essex 3*. Yet they are not, with the paradoxical result that listeners hearing only *Sussex 2...* can turn off the radio because they already know the score. It is probable that announcers seeing the symmetrical segmental structure XY ZY before them assign it a (cognitively inappropriate but esthetically motivated) noniconic symmetrical intonation XyZy.

Because the results of an iconic imperative are constantly being eroded by other drives, and compromised in any event by the natural limitations of the one-dimensional auditory medium of language, cases in which it is nevertheless apparent are heuristically useful. A routinely exploited heuristic consequence of the principle of isomorphism is that recurrent cross-linguistic identity of form between two or more grammatical constructions must be a reflection of a perhaps unsuspected semantic commonality; for example, such a commonality is exhibited by protasis clauses in conditional sentences and sentential topics, whose semantic identity is now widely recognized (cf. Podlesskaya, 1992). A parallel heuristic consequence of the principle of motivation is that when a given construction recurrently exhibits formal symmetry, this formal symmetry is a reflection of possibly unsuspected conceptual symmetry; such a pattern is exhibited by the protasis and apodosis clauses of counterfactual conditional sentences, and a plausible semantic account for this symmetry has been offered by Haiman and Kuteva (2003).

Given that iconicity is widespread in human languages and given that the forces of conventionalization immediately attack and destroy iconicity, the central problem is accounting for the fact that it nevertheless endures. For this to be so, it is not enough to suggest that iconicity was the original state of some conjectured proto-language. Rather, iconicity must be constantly created. Although it has been optimistically proposed that there are cognitive motives for iconicity, no evidence has ever been presented that iconic

forms are easier to store or to access than symbolic ones. This suggests that an essentially esthetic impulse (perhaps simply the impulse to reproduce a given structure) is responsible for the creation of iconic forms (cf. Haiman, to appear).

Identity and Language

J E Joseph, University of Edinburgh, Edinburgh, UK

© 2006 Elsevier Ltd. All rights reserved.

This article considers what identities are, how they depend on language, how that dependency may have come about, and how linguistics and affiliated disciplines have gone about analyzing it. Secondly, it examines how the very way in which we identify and conceive of languages is bound up with identity, usually that of a nation.

What Is Identity?

Your identity is, very simply, who you are. It has two basic aspects: your name, which serves first of all to single you out from others (the deictic function), and then that deeper, intangible something that constitutes who you *really* are, which we might think of as the *meaning* of your name (the semantic function). Names are obviously pieces of language, but less obvious is the role played by the language you speak, and how you speak it, in constructing that other, deeper aspect of your identity, both for yourself and others.

Imagine a group of strangers at a bus stop. The bus they are waiting for drives past without stopping, and the following remarks ensue:

A: Well fuck me.

B: I say, wasn't that the 23?

C: I'm like not believing this.

Picture in your mind what A, B, and C look like. You can probably say something about how they are dressed, their background, what they do, what they are like, and whether you would like them or not.

It is extraordinary how much we are able to infer from what are, after all, a few squiggles on a page. We have an instinctive capacity to construct the identity of a whole person in our minds based on minimal input, and it is most effective when the squiggles represent something the person said.

Self-identity has long been given a privileged role in identity research. But the identities we construct for ourselves and others are not different in kind, only in the status we accord them. The gap between the identity of an individual and of a group – a nation or town, race or ethnicity, gender or sexual orientation, religion or sect, school or club, company or profession, or the most nebulous of all, a social class – is most like a true difference of kind. Group identities seem more abstract than individual ones, in the sense that 'Brazilianness' doesn't exist separately from the Brazilians who possess it, except as an abstract concept. Yet combinations of such abstractions are what our individual identities are made of, and group identity frequently finds its most concrete manifestation in a single, symbolic individual. The group identities we partake in nurture our individual sense of who we are, but can also smother it.

Bourdieu, discussing regional and ethnic identities, made an important point that applies to many other types of identity as well: although they essentialize what are actually arbitrary divisions among peoples, and in this sense are not 'real,' the fact that, once established, they exist as mental representations makes them every bit as real as if they were grounded in anything 'natural.'

One can understand the particular form of struggle over classifications that is constituted by the struggle over the definition of 'regional' or 'ethnic' identity only if one

transcends the opposition [...] between representation and reality, and only if one includes in reality the representation of reality, or, more precisely, the struggle over representations [...].

Struggles over ethnic or regional identity – in other words, over the properties (stigmata or emblems) linked with the *origin* through the *place* of origin and its associated durable marks, such as accent – are a particular case of the different struggles over classifications, struggles over the monopoly of the power to make people see and believe, to get them to know and recognize, to impose the legitimate definition of the divisions of the social world and, thereby, to *make and unmake groups* (Bourdieu, 1991: 221).

The role played by names, labels, and other linguistic forms of classification-*cum*-text in the making and unmaking of groups along the lines Bourdieu described is why identity is ultimately inseparable from language.

Identity and the Functions of Language

Dunbar (1996) located the origin of language in the needs of higher primates to form social alliances in order to deal with challenges in their environment, including threats from powerful members of their own species. He believes that the essential functions of language for evolutionary purposes were phatic ones, with gossip – language of purely social content exchanged for social purposes – being the equivalent of the grooming that primates use to form and maintain social bonds. The move from physical to linguistic grooming is attributed by Dunbar to increasing group size. Early humans “must have faced a terrible dilemma: on the one hand there was the relentless ecological pressure to increase group size, while on the other time-budgeting placed a severe upper limit on the size of groups they could maintain” (Dunbar, 1996: 77). Language made it possible to increase group size without losing social cohesion or the time needed to gather and hunt food. Because language can be directed at several people simultaneously, the rate of grooming is increased manifold.

Dunbar notes, “Being able to assess the reliability of a prospective ally becomes all-important in the eternal battle of wits” (Dunbar, 1996: 78–79). On the one hand, language serves the purposes of the individual who is seeking to make an alliance: “It allows you to say a great deal about yourself, your likes and dislikes, the kind of person you are; it also allows you to convey in numerous subtle ways something about your reliability as an ally or friend” (Dunbar, 1996: 78). It also serves the person being courted as a prospective ally: “Subtle clues provided by what you say about yourself – perhaps even how

you say it – may be very important in enabling individuals to assess your desirability as a friend. We get to know the sort of people who say certain kinds of things, recognizing them as the sort of people we warm to – or run a mile from” (Dunbar, 1996: 79). He concludes, “Language thus seems ideally suited in various ways to being a cheap and ultra-efficient form of grooming. [...] language evolved to allow us to gossip” (Dunbar, 1996: 79).

If we think about language from this perspective, its primary purpose is no longer necessarily restricted to one of the two traditionally ascribed to it, communication (by a speaker having an intention and wishing to transmit it to listeners) and representation (of the universe, as analyzed into the logical categories that languages are thought to contain). Before either of these, and in many regards enveloping them both, language exists, in this reversed perspective, for the purpose of *reading the speaker*.

Sociolinguistic inquiry into identity and language is concerned with how people read each other, in two senses. First, how the meanings of utterances are interpreted, not just following idealized word senses and rules of syntax as recorded in dictionaries and grammars, but in the context of who is addressing whom in what situation. Secondly, how speakers themselves are read, in the sense of the social and personal identities their listeners construct for them based on what they say and how they say it (a complex process, because most speakers’ output is already shaped in part by how they have read their listeners). Every day each of us repeatedly undertakes this process of constructing our reading of people we encounter, in person, on the telephone, on the radio or the screen, or in writing, including on the Internet, based on their language – what they say and how they say it.

Targeting Identity in the Analysis of Language

Modern linguistics has moved slowly but steadily toward embracing the identity function as central to language. The impediment has been the dominance of the traditional outlook, which takes representation alone to be essential, with even communication relegated to a secondary place. This outlook was never the only one available, however, and when early 20th-century linguists such as Jespersen and Sapir came to investigate how language functions to define and regulate the role of the individual within the social unit at the same time that it helps to constitute that unit, they were not without predecessors. It was just that mainstream linguistics as it had developed within the 19th century was not inclined to see such questions as falling within its purview.

An overview of the development of such inquiry within linguistics and adjacent fields can be found in Joseph (2004), from which some key moments will be excerpted here. The first is Labov (1963), a study of the English dialect of Martha's Vineyard, an island off the coast of Massachusetts, where the diphthongs in words such as *right* and *house* are pronounced as [əy] and [əw] rather than [ay] and [aw]. This feature is not found in the dialects of the mainlanders who 'summer' on Martha's Vineyard, and with whom the Vineyarders (year-round residents) have a complex relationship of dependency and resentment. "It is apparent that the immediate meaning of this phonetic feature is 'Vineyarder.' When a man says [rəyt] or [həws], he is unconsciously establishing the fact that he belongs to the island: that he is one of the natives to whom the island really belongs" (Labov, 1963: 307). This is very much the sort of analysis of the effect of linguistic identity on language form that would characterize work in the 1990s and since, though it was sidelined in the mid-1960s by the statistical charting of variation and change.

In the meantime, one particular identity focus – gender – led the way in directing attention to the reading of identity in language. Lakoff (1973) argued that, in both structure and use, languages mark an inferior social role for women and bind them to it. Gender politics is incorporated directly into the pronoun systems of English and many other languages, through the use of the masculine as the 'unmarked' gender (as in 'Everyone take his seat'). Lakoff points to features that occur more frequently in women's than in men's English, such as tag questions, hedges, intensifiers, and pause markers, which as marks of insecurity and of the role women are expected to occupy are fundamental to maintaining the status quo in gender politics.

As the notion of separate men's and women's language was accepted, the more general notion of the language–identity link was let in through the back door, leaving the way open for the study of group identities of all sorts beyond those national and ethnic ones traditionally associated with language difference. This was a challenge to a sociolinguistics that had been fixated on class differences. By the mid-1980s this shift was underway in the work of, for example, Gumperz (1982), Edwards (1985), and Le Page and Tabouret-Keller (1985), though it was really in the 1990s that it would come to occupy the mainstream of work in sociolinguistics and linguistic anthropology. (For a small but representative sample of studies see, on the sociological end, Fishman (1999); on the anthropological, Schiefelin *et al.* (1998); and in discourse analysis, Wodak *et al.* (1999).)

This work also received significant input from social psychology, where one approach in particular needs to be singled out: Social Identity Theory, developed in the early 1970s by Tajfel. In the years following his death in 1982, it came to be the single most influential model for analyzing linguistic identity. Tajfel (1978: 63) defined social identity as "that part of an individual's self-concept which derives from his knowledge of his membership of a social group (or groups) together with the value and emotional significance attached to that membership." Within this simple definition are embedded at least five positions that in their time were quite revolutionary: that social identity pertains to an individual rather than to a social group; that it is a matter of *self-concept*, rather than of social categories into which one simply falls; that the fact of *membership* is the essential thing, rather than anything having to do with the nature of the group itself; that an individual's own knowledge of the membership, and the particular value they attach to it – completely 'subjective' factors – are what count; and that emotional significance is not some trivial side effect of the identity belonging but an integral part of it.

Beyond this, Social Identity Theory marked a break with other approaches in the fact that it was not concerned with analyses grounded in a notion of 'power,' but simply in the relative hierarchizations that people seem instinctively to impose on ourselves, most particularly in our status as members of 'in-groups' and 'out-groups,' which would come into even greater prominence in the 'Self-Categorization Theory' that developed as an extension of the original model, notably in the work of Tajfel's collaborator Turner (see Tajfel and Turner, 1979; Turner *et al.*, 1987; Turner, 1991).

Partly under the influence of such work, sociolinguists were beginning to reorient their own object of investigation. Milroy (1980) reported data from studies she conducted in Belfast showing that the 'social class' of an individual did not appear to be the key variable allowing one to make predictions about which forms of particular linguistic variables the person would use. Rather, the key variable was the nature of the person's 'social network,' a concept borrowed from sociology that Milroy defined as "the informal social relationships contracted by an individual" (Milroy, 1980: 174). Where close-knit localized network structures existed, there was a strong tendency to maintain nonstandard vernacular forms of speech – a tendency difficult to explain in a model such as Labov's, based on a scale of 'class' belonging where following norms of standard usage marked one as higher on the hierarchy and entitled to benefits that most people desire. Labov's early work on Martha's

Vineyard had suggested that the answer lay in identity, specifically in the value of belonging to a group who, although not highly placed in socioeconomic terms, could nevertheless claim something valuable for themselves (in the Martha's Vineyard case, authenticity). Milroy's book provided statistical backing for such an explanation.

Although the inner workings of the social network depend somewhat on the amount of personal contact, the essential thing is that its members share *norms*. As attention turned to understanding the nature of these norms, two much publicized views had an impact. Fish (1980) had devised the concept of the 'interpretative community' to account for the norms of reading whereby people evaluate different readings of the same text as either valid or absurd. An interpretative community is a group sharing such a set of norms; its members may never come into direct physical contact with one another, yet share norms spread by the educational system, books, or the media. Soon after, Anderson (1991, first published in 1983) proposed a new understanding of the 'nation' as an 'imagined community,' whose members, like that of the interpretative community, will never all meet one another let alone have the sort of regular intercourse that creates a 'network.' What binds them together is the shared belief in the membership in the community.

Notably with the work of Eckert, sociolinguistic investigation of groups ideologically bound to one another shifted from statistically based examination of social networks to more interpretative examination of 'communities of practice,' defined as "an aggregate of people who come together around mutual engagement in an endeavor" (Eckert and McConnell-Ginet, 1992: 464). In the course of this endeavor there emerge shared beliefs, norms, and ideologies, including, though not limited to, linguistic and communicative behavior. The advantage of the community-of-practice concept is its openness – any aggregate of people can be held to constitute one, so long as the analyst can point convincingly to behavior that implies shared norms or, better still, elicit expression of the underlying ideologies from members of the community. This line of research is thus continuous with another one that has focused more directly on the normative beliefs or ideologies by which national and other group identities are maintained. Some early work along these lines was published in Wodak (1989) and Joseph and Taylor (1990), and subsequently a great deal more has appeared, e.g., in Verschueren (1999), Blommaert (1999), and Kroskrity (2000).

Other features of recent work on language and identity include the view that identity is something constructed rather than essential and performed

rather than possessed – features that the term *identity* itself tends to mask, suggesting as it does something singular, objective, and reified. Each of us performs a repertoire of identities that are constantly shifting, and that we negotiate and renegotiate according to the circumstances.

Coconstructing National Identity and Language

As mentioned at the outset, it is not simply the case that identity is built upon language. The reverse is also true. One of the first obstacles to be overcome in establishing a national identity is the nonexistence of a national language. The 'nation-state myth' – that basic view of the world as consisting naturally of nation-states – is bound up with an assumption that national languages are a primordial reality. Whatever difficulty we might have in determining the borderlines of who 'the Germans' are, whether the German-born children of Turkish immigrants are German for instance, or whether certain Alsatians are French or German, the German language is going to figure significantly in the equation. Hitler attempted to justify his initial invasions of neighboring countries on the grounds that these German-speaking peoples were inherently part of the German nation; and, as Hutton (1999) has shown, his policies of oppression and ultimately extermination of the Jews were underpinned by the argument that, although their language, Yiddish, was a form of German, their lack of a nation gave them the perverse racial peculiarity of not being able to have a 'mother tongue.' They therefore did not belong to the German body politic but were seen as a parasite within it.

But whether Bohemian, Alsatian, and Yiddish dialects were part of 'the German language' were not facts given in advance, nor even ones that a linguist could establish scientifically. The 'German language,' like every national language, is a cultural construct. It dates from the 16th century and is generally credited to Luther, who, in translating the Bible, strove to create a form of German that might unite the many dialect groups across what until the late 19th century was a patchwork of small and large states, linguistically very diverse. (This story is itself a part of the cultural construct, and although not false, it is considerably oversimplified – in order to shape up as a proper 'hero' myth, it ignores or marginalizes the work of many other individuals and broader cultural changes.) The prototype of the modern national language was Italian, which may seem surprising, given that Italy did not become a political nation until 1860, with full unification coming in 1870, just a year before that of Germany. Or perhaps not so surprising – the political divisions of the Italian

peninsula may have been precisely what motivated the creation of cultural unity through linguistic means.

In the Romance-speaking world during the thousand years from the fall of the Roman Empire to the Renaissance, 'language' meant Latin, used for all official and written purposes, though what people spoke in nonofficial contexts was a local dialect, historically related to Latin though significantly different from village to village. There was, then, no 'Italian language.' That concept and its realization are credited – heroically, and again only semimythically – to Dante, author of the *Divina Commedia*. Dante's treatise *De vulgari eloquentia* (c. 1306), not published until 1529, lays out the process by which he claimed to discover, not invent, the national language of a nation that would take five and a half centuries to emerge politically. To the modern reader this all seems a fiction, a pretense of discovery in what will actually be Dante's invention of an illustrious vernacular – which will in turn camouflage how much of it is actually based on his native Tuscan. But Dante's *volgare illustre* became the template on which other modern European standard languages were modeled.

Once the national languages existed, however, their invention was promptly forgotten. The people for whom they represented national unity inevitably came to imagine that the language had always been there, and that such dialectal difference that existed within it was the product of recent fragmentation, when in fact it had preceded the unification by which the national language was forged. In the words of one prominent historian:

National languages [...] are the opposite of what nationalist mythology supposes them to be, namely the primordial foundations of national culture and the matrices of the national mind. They are usually attempts to devise a standardized idiom out of a multiplicity of actually spoken idioms, which are downgraded to dialects [...]. (Hobsbawm, 1990: 51)

By the early 19th century this 'nationalist mythology' would lead to strong Romantic theorizations of national political identity being grounded in a primordial sharing of language. One of the strongest expressions was that of Fichte:

The first, original, and truly natural boundaries of states are beyond doubt their internal boundaries. Those who speak the same language are joined to each other by a multitude of invisible bonds by nature herself, long before any human art begins; they understand each other and have the power of continuing to make themselves understood more and more clearly; they belong together and are by nature one and an inseparable whole. (Fichte, 1968 [1808]: 190–191)

Fichte was writing to rouse the 'German nation' to repel the advance of Napoleon. He was successful in doing so. However, in 1870 the shoe was on the other foot, when the Franco-Prussian War led to the German annexation of Alsace, a German-speaking province that had been part of France for more than two centuries and whose population was mainly loyal to France, despite their linguistic difference. This provoked a sharp turn away from the Fichtean view on the part of French linguists such as Renan (1882), who formulated a new view of national identity as based not on any primordially determining characteristic such as language, but on a shared will to be part of the same nation, together with shared memories.

The nation, in other words, exists in the *minds* of the people who make it up. This is the conception that Anderson (1991: 6) would return to in defining the nation as "an imagined political community." The 'legacy of memories' Renan pointed to would dominate future philosophical and academic attempts to analyze national identity. The other element, the collective 'will' of the people, would, however, have the deepest political impact, starting with the redrawing of the map of Europe at Versailles in 1919. It has continued to be the assumed basis for the legitimacy of the political nation up to the present time.

Billig, a colleague and collaborator of Tajfel, has explored how the "continual acts of imagination" on which the nation depends for its existence are reproduced (Billig, 1995: 70), sometimes through purposeful deployment of national symbols, but mostly through daily habits of which we are dimly aware at best. Examples include the national flag hanging in front of the post office and the national symbols on the coins and banknotes we use each day. Billig introduced the term *banal nationalism* to cover the ideological habits that enable the established nations of the West to be reproduced. In Billig's view "an identity is to be found in the embodied habits of social life" (Billig, 1995: 8), including language. Smith (e.g., 1998, Chapter 8) has emphasized how much of the effort of nationalism construction is aimed at reaching back to the past in the interest of 'ethno-symbolism,' and this can be seen particularly in the strong investment made by modern cultures in maintaining the 'standard language,' by which is meant a form resistant to change, hence harking backward. Hobsbawm placed great stress on the fact that enthusiasm for linguistic nationalism has historically been a phenomenon of the *lower middle class*.

The classes which stood or fell by the official use of the written vernacular were the socially modest but educated middle strata, which included those who

acquired lower middle-class status precisely by virtue of occupying non-manual jobs that required schooling. (Hobsbawm, 1998: 117)

These are also the people who become the mainstay of nationalism – not just by active flag-waving on symbolic occasions, but daily in the banal ways pointed to by Billig, including their use of ‘proper language’ and their insistence on its norms, for instance in conversation with their own children. Hobsbawm has suggested that, in Victorian times, the pattern was established whereby the lower middle classes (artisans, shopkeepers, and clerks) enacted their national belonging by showing themselves to be “the most ‘respectable’ sons and daughters of the fatherland” (Billig, 1998: 122). In other words, although their real identity was that of a social class, they masked it for themselves and others in a nationalistic guise. The mask was double-sided: in their obsession with ‘speaking properly’ as a mark of respectability, they were contributing to the linguistic construction of their nation.

At the start of this article, I wrote that identities are, first and foremost, names, and that the work of identity construction consists of supplying meaning for the name. In the case of national identity, language has traditionally been a key ingredient in this process for at least five reasons:

1. Groups of people who occupy contiguous territory and see themselves as having common interests tend to develop, over long stretches of time, ways of speaking that are distinctive to them, marking them out from groups who either are not geographically adjacent to them or else are perceived as having different, probably rival, interests. In other words, language does tend to mark out the social features on which national belonging will come to be based – but it is only a tendency, because it also happens very frequently that the same way of speaking is shared by people with very different interests (religious ones, for instance), and that markedly different ways of speaking exist among a group of people who nonetheless see themselves as part of the same nation.
2. The ideology of national unity has favored a view that nations are real because those within them share a deep cultural unity, and this has coexisted with a widespread – indeed, nearly universal – belief that deep cultural unity is the product of a shared language. This is what Fichte meant by the ‘invisible bonds’ by which nature has joined those who speak the same language. Again, as with (1), it cannot be more than a tendency, because it is not the case that people who identify themselves as belonging to the same culture or nation think

identically. Yet language is central to the *habitus* (an ancient term revived by Bourdieu): the fact that we spend our formative years attending long and hard to the task of learning words and their meanings from those around us results in our acquiring tastes, habits, and ways of thinking from them that will endure into adult life. The language does not somehow transmit culture and identity to its speakers – rather, the language is the *text* through the constant interaction with which older speakers transmit culture and identities (local and personal as well as national, ethnic, and religious) to the young. (In many cases the young will want an identity of their own and will attain it first of all by resisting the imposition of culture upon them by their elders.)

3. In addition to being the text of cultural transmission, the language is the principal medium in which texts of national identity in the more usual sense will be constructed. It is not the only such medium, nor the only powerful one, as Billig’s exposition of ‘banal nationalism’ has shown. But the particular concepts that constitute a national identity correspond to words in the national language, embodied in ‘sacred texts’ of the nation such as a constitution or key works of the national literature, including the national anthem.
4. As universal education is adopted throughout the nation, inculcating standards of ‘correct’ language assumes a central role. Overtly, this is from a perceived duty to maintain the culture. However, as Hobsbawm has shown, such is the force of the language-culture-nation-class nexus that, especially for the upwardly mobile members of the lower middle class, being a ‘proper’ citizen and member of the community is inseparable from using ‘proper’ language.
5. Insofar as nations are not the historical essences they purport to be, but are constructs that inevitably involve a certain amount of arbitrary and even capricious divisions and classifications, when a nation wants to control who can live in it, vote in it, and enjoy state benefits, language can appear to be the most obvious test for deciding whether particular individuals belong to the nation or not. Most nations no longer have laws based on racial classification – which are rarely easy to apply in any case – yet many do require cultural qualifications to be met, which are likely to include language either overtly or indirectly.

Each of these factors has reinforced the others in giving the national language the force of a cultural-historical ‘ethno-symbolic’ myth as suggested by Smith (see earlier discussion). Within each, too, there

is a contradiction or a caveat that has periodically pendulum-swung to prominence, such that the loss of belief in the national language and all it stands for is always potentially there and is bound to come to the fore at least periodically. The question that is unanswerable for now is whether national languages, together with the nations to which they are attached, represent a historical phase that is now on a course of decline heading for eventual disappearance, to be replaced with 'glocalization' – a term that has been coined to denote the combination of globalization with the resurgence of local, subnational sites of belonging – or whether they are an invention that has proven too useful for human social organization to be given up.

Reflections of Identity in Language Use

The main focus of studies of language and identity in sociocultural anthropology (LISA) is on the interplay between global cultural categories ('census identities' such as gender, race, class, or others that may be culturally salient, such as kinship identities), and how these identities are constructed, performed, or challenged locally in speech events through linguistic forms. One of the distinguishing characteristics of the LISA approach is that rather than taking census and other identity categories as pre-given, it investigates how these categories are made relevant by and for language users. It is important to understand that LISA research does not lose sight of the larger picture; it attempts to discover how speakers' ideologies about census identities shape, and are shaped by, interaction. Identity as viewed in this tradition is therefore emergent but constrained: identities are created and re-created when speakers are actually talking to each other, but the way these identities emerge is contingent on the speakers' sociocultural discourses and ideologies.

Identities are named 'relationships' in cultural ideologies and interactions; identity categories such as census identities are a shorthand for identifying – and thinking about – the many ways that a person relates to others in the community. For example, by referring to gender or drawing on a gender identity in interaction, a person calls up a bundle of culturally-shared relationships to other people in their culture. A man may call up solidarity with another man through cultural ideologies of masculinity that identify men as a class of people who share certain social traits. In this sense, identities are 'imaginary' (cf. Anderson, 1991 on imagined communities and nationalism) or 'figured worlds' (Holland *et al.*, 1998). Because identities are relational, a person has no single fixed identity, only identities constructed and contextualized in interaction (and to the extent that an identity is psychologically real, it is based on the self's conception of its place in psychologically idealized models of interaction). LISA studies investigate the tension between ideologies of identity categories and their emergence in interaction through language and other communicative modes. LISA does not study the motivation of speakers to join identity categories, but it does show how such categories are reproduced in ideologies and cultural discourses through talk.

We might suppose that the most straightforward way of claiming an identity is to speak the language of that identity: one is Tongan when one speaks Tongan, Uzbekh when one speaks Uzbekh, etc. But this view is destabilized when speakers are multilingual (which seems to be the larger portion of the world's population). Does a Black-American-Heterosexual-Woman become Dominican when she uses Dominican Spanish, or an Australian when she uses Australian English? By investigating just these kinds of situations (Bailey, 2001) LISA researchers have shown that the 'language-equals-identity' model is too simple to represent actual interaction. This research challenges the notion that languages are single, invariant entities, and has shown that a language is full of many different voices: registers, styles, varieties, and even other languages. At the same time, LISA analyses incorporate speakers' own ideologies of language. For although we might objectively observe that language use is never pure, the subjective ideologies of language users is often quite different. Language users' understandings of "how language is supposed to be" affect the way they use it: they bias performance in certain directions, as sociolinguistic variationists have been able to measure.

The terms most used for such a mixed view of language in LISA are heteroglossia and polyphony, from the work of Russian literary theorist Mikhail Bakhtin. Bakhtin (1981) argued that words (and by extension other linguistic forms) carry the 'voices' of previous uses, into current contexts of use. That is, words have meanings beyond pure denotation and carry the residue of earlier situations of use. Heteroglossia, as Bakhtin uses the term, refers to the tension between the pure official language and more vernacular forms of language existing in a language community and used in a single text. Polyphony refers the use of different languages or varieties that meet on an equal footing (cf. Morris, 1994: 248–249). Bakhtin's focus was the novel, but LISA researchers have shown that heteroglossia and polyphony obtain in everyday conversation, and these properties of language help people to create identities in interaction. This view destabilizes both the simplistic view of 'a language,' and the assumption that by using a particular linguistic feature (e.g., word, pronunciation, or syntactic construction), one can perform an identity connected with a culturally-relevant population that is thought to use that linguistic feature.

Meanings that rely on the current or previous context, or both, are known as indexical meanings. All languages have such indexical meanings as part

of their grammar. In English, the meanings of words such as *I* and *you* are associated with actual people only in the moment of speaking. Thai pronouns indicate not only speaker and addressee, but also their relative ages and genders (Simpson, 1997). Most indexical meanings – whether in a grammar or not – relate to the aspect of context that provides information about the speaker's identity. A linguistic feature indexes an identity because someone of that same culturally-relevant identity category has used it before, or has been represented as using it before (e.g., in media). Speakers rarely assert **directly** that they are, for example, a woman, or white, or Bosnian (although they do at times, and these moments are all the more interesting for their rarity). Rather, speakers more often rely on the processes of indexicality to create their identities.

Theorizing indexical meaning as it relates to identity has been the focus of much of the work of Michael Silverstein (1976, 1996) and Elinor Ochs (1992, 1993), who have made a number of important distinctions among indexical meanings that are crucial for understanding how identity and language are theorized. The first distinction is between direct and indirect indexicality (Ochs, 1992). Direct indexicality is a meaning relationship that holds directly between language and the stance, act, activity, or identity indexed. For example, in English, using certain syntactic forms such as imperatives will generally directly index a relationship of power. The imperative is associated with the context of a speaker who has the power to force the addressee to perform the action stated in the imperative. Indirect indexicality arises when the social relationship (in this case, power) is further indexed to an identity category, such as masculinity. Thus we might notice that men use more imperatives than women, or there might exist (as in the United States) a cultural discourse such that men are supposed to be more authoritative than women. When this supposed connection is discovered, we might be tempted to say that imperatives index masculinity; however, it would be more accurate to say that imperatives indirectly index masculinity because they directly index power, and power is in turn associated with masculinity.

An illustration of this process can be seen in the American English address term *dude* (Kiesling, 2004). *Dude* is used most frequently by young white men, and indexes a stance of casual solidarity: a friendly, but crucially not intimate, relationship with the addressee. This stance of casual solidarity is a stance habitually taken more by young white American men than other identity groups. *Dude* thus indirectly indexes young, white, masculinity as well.

Such descriptions of indexicality are abstract, however, and do not take into account the actual context of speaking, such as the speech event and the identities of the speakers determined through other perceptual modes, such as vision. One of the most difficult aspects of indexicality is that indexes not only call up the previous contexts in which a linguistic feature has been used, but what previous context they call up can be influenced by the current context. Indexical meanings thus interact with the context of speaking, such that the (assumed or 'pre-existing') identity of the speaker can affect the indexicality of a form even as that form is seen as performing an identity. For example, in the United States, often when a woman uses an imperative, a particular kind of authority – motherhood – is indexed: when a woman tells a friend (particularly a man) to "put on your coat," the response is often sarcastically, "Yes, mother." In this example, the use of an imperative directly indexes a stance of authority. In the dominant American cultural discourses of femininity, authority is indexed only in the context of motherhood, so this feminine role is indirectly indexed and available for comment by the addressee of the imperative. Such a response is not made when the speaker is known to be a man (unless the addressee wishes to refigure the speaker as a woman for some reason, in which case the layers of indexicality begin to become thick and tangled). One might argue that the content of the imperative is what indexes motherhood: mothers order their children to do things for the children's own good, especially putting on coats. This argument only points out just how specific indexicality can be, however, as a single phrase can call up the stereotypical class of people known in the United States as 'mothers.' In addition, we might observe that imperatives used by women are more often than not used with such 'motherly' content. In any case, note how even such a brief, unremarkable use of language leads to an intricate web of identity indexes. Such are the minute, commonplace, but complex indexical meanings that rely on and recreate identity discourses and ideologies.

These indexicalities are thus both sensitive to and indexical of social context and the other possible relevant identities being performed in a particular instance of talk-in-interaction. Bonnie McElhinny's (1994) study of police officers in Pittsburgh, Pennsylvania, is particularly relevant in this light. She showed that when the identity of being a police officer is salient in an interaction, such a speaker tends to use less affect in her or his speech. This lack of affect indexes a distant, emotionless stance, a stance that is not indexical of femininity in Pittsburgh. However, the

women officers told McElhinny that they did not feel less feminine in these situations, because gender is less relevant as an interactional identity; in such interactions they think of themselves primarily as police officers. As women have joined men on the police force, the affectless and emotionless stance has thus come to index not so much masculinity, but 'police officer.'

Further complicating the connections between linguistic form and identity is the fact that indexes are always potentially creative as well as presupposing (Silverstein, 1976). That is, an index can be used to change what is in play in the context (creative) rather than simply respond to the already mutually understood context (presupposing). The classic example of such context-changing uses is that observed by Blom and Gumperz (1972) in Hemnesberget, Norway. In Hemnesberget at that time there was a diglossic situation in which the linguistic variety of Norwegian known as Bokmål was the official language of government and commerce, while Ranamål was the local variety (dialect) more typically used for intimate settings. Blom and Gumperz described an instance in which an inhabitant goes to the community office for official business and interacts with another local inhabitant with whom he is friends. The official business is conducted in Bokmål (indexing in a presupposing manner the situation), but when the official business is finished, the customer switches to Ranamål to indicate he wishes to have a less formal conversation about local matters. This switch from Bokmål to Ranamål is a creative index, because it changes the context from formal to informal, rather than responding to an external cue such as a change of setting or the arrival of a new participant.

While this distinction between creative and presupposing indexicality is important and useful to begin with, LISA researchers have more recently emphasized the fact that indexes always have both a creative and a presupposing aspect. Sidnell (2003), for example, described how language is used to create a male space in a Guyanese rum shop. While this setting is understood by the Guyanese to be a male space, it is nonetheless often populated by women for various reasons. Sidnell analyzed a stretch of talk-in-interaction in which one of the men drinking in the rum shop designs "his talk...to preserve the observable gender exclusivity of the activity" (2003: 338). That is, the way his talk is designed makes the space a male one even when he is addressing a woman in it, and thereby helps to recreate the 'male-only' context, in effect (creatively) peripheralizing women who are present.

A final complication comes from the 'level' of knowledge that speakers use in interpreting indexical meaning. While most indexical meanings are not overtly discussed by speakers, some linguistic features nevertheless become the focus of social discussion and overt knowledge. For example, Americans have become aware of, and can articulate, the masculine indexicality of *dude* (they are aware of its use on this societal level), but have much more trouble explaining what it means in terms of local stances. Morford (1997) analyzed the use of second-person pronouns in French in this light. She showed that on one level of indexicality, the use of *tu* and *vous* in French indexes a relationship between two speakers based on a reciprocal vs. asymmetric use of the forms. However, Morford found that French speakers have a knowledge about (for example) what kinds of families have asymmetric use between parents and children, and that some speakers make conscious choices about whether to use *tu* or *vous* with other speakers. Most importantly, these choices have to do with the interplay between this metapragmatic awareness and the kinds of identities that speakers wish to create. Morford cites one particularly vivid example of a teacher who explains that he constructs status as a teacher in part through his asymmetric use of second person address with the support staff of the school.

Performance of Identity in Mediated Social Practice

While the distinctions made above are important, individual indexical forms such as 'pronoun' or 'accent' are idealizations of meanings that are tangled in a messy, changing, and locally contestable web of meaning. That is, there are complex meaning relationships not just between a linguistic form and a specific social identity, but that there are also connections of meaning among different kinds of identities, and different social entities and categories such as institutions and census groups. LISA researchers do not search for psychological representations of such links, but rather they investigate the manner in which such connections are created and used in interaction. In fact, these connections need not be present in any individual's psyche before a speech event; it is by participating in the event itself that speakers bring indexicalities and identities about, because they are needed for speakers to 'make sense' of the talk. In this way, LISA is similar to critical discourse analysis (see **Critical Discourse Analysis**) in arguing that the interpretations that speakers make of the ongoing talk based on 'background knowledge' or conversational principles (see **Pragmatics: Overview**) are not

used in a value-free way but are a resource for doing identity in interaction.

One of the most significant bodies of work along these lines is Jane Hill's (1993, 1995, 1998) work on what she calls "mock Spanish." (see Hill, Jane). In this work, the process of indirect indexicality and the ideological structuring of background knowledge come together to reproduce racist discourses that are covert even for those using them. Hill took as her starting point the nonce borrowing of Spanish (or forms that resemble Spanish) by Anglos, such as *Hasta la vista, baby*, popularized by actor and politician Arnold Schwarzenegger in the film *Terminator*. Hill showed that these forms of Spanish are used strategically by speakers to create an ironic speaker stance with respect to stereotypically Hispanic (Latino) identity, stances that are often demeaning to this identity category (e.g., lazy, disorderly, given to rudeness), in effect distancing the self from such identities by gently parodying their principal index, Spanish language forms.

A similar process is at work in a conversation I analyzed between two white American fraternity men (Kiesling, 2001). The two men in that conversation discuss the roster of the fraternity's intramural basketball team. Embedded in this discussion is a short exchange in which each boasts about his basketball ability. At strategic points in both parts of this speech event, the interactants use linguistic features of African American Vernacular English (AAVE) to index their boasting stance, as well as a stance of basketball expertise. The crucial point is that the men are not trying to 'be black,' but they are drawing on an association of 'blackness' with basketball and boasting. In other words, when performing 'basketball player' it helps to perform 'black' as well. A similar point was made by Bucholtz (1999), who showed that AAVE features are used in a fight narrative told by a white male high school student in California to represent a tough stance. Other articles appearing in the same journal issue as Bucholtz's made similar points and represent an important body of work for LISA understandings of language and identity.

Issues of race and racism in language, and gender and sexism in language have therefore been central in LISA research. Over the past decade, Susan Gal and Judith Irvine (Gal and Irvine, 1995; Irvine, 2001) have developed an influential set of concepts for understanding how speakers' ideologies of language are involved in the social production of indexicals of identity categories. Their view recognized three semiotic effects of ideology as a factor in indexicality: iconicization, recursivity, and erasure. Iconicization is the ideological endowing of a linguistic feature

with and characteristic that is taken to be like some essence of a recognizable identity or type of person. In the example from Hill above, mock Spanish is understood to be iconic of some inherent characteristic, laziness or disorderliness, of Spanish speakers. Recursivity is the manner in which ideologies are represented in parallel recurring form with respect to multiple levels of social organization. In the example above, stereotyped differences between black and white men in the United States (the stereotyped black characteristics of athletic prowess and fighting ability) become the basis for negotiating differences between fraternity brothers, both of whom are white. In effect this use recursively reproduces the black-white identity distinctions in interactions with only white male speakers. Finally, erasure is the effective simplification of both formal and sociological complexities of experience, and can render all but a single term of a schematic dichotomization invisible to speakers. In all of the above examples, the Anglo white language style is invisible as a specifically alternative register, while the Spanish and AAVE are marked and highly salient; the white Anglo vernacular register is erased and re-enforced as normative by such uses, rendering its social peripheralizing power less visible.

Studying Identity through Language and Contextualized Language Variation

Up to this point, we have generally focused on language and identity as performed when speakers use languages or varieties they recognize as different. But the processes of indexicality, and the tendencies toward iconization, recursivity, and erasure are at work even when a single variety is being used, not only when varieties (or languages) are mixed. As sociolinguistic variationists continually remind us, language is inherently variable in both grammar and use (Guy, 1996); such variability is a valuable resource for speakers in identity work. Several researchers have been incorporating insights from LISA studies into the search for how this variability is used by speakers to create social meaning.

Penelope Eckert (2000, 2002) is the most prominent of these researchers and has done the most to move this new perspective of meaning in variation forward. She advocates understanding variation as a resource for creating personal styles and "stylistic practice as a process of *bricolage*, in which ways of being are transformed through the strategic reuse of meaningful resources." (2002: 5) In her ethnographic analysis of sociolinguistic variation in a Detroit-area high school, she showed how vowel variants vary alternately with other aspects of social

practice and style, such as ‘cruising’ (driving around a particular route with friends without a destination) and wearing wide pants cuffs. She showed that while the variables she analyzed have general meanings throughout the school (e.g., whether they are associated with the urban rather than suburban areas of Detroit), they are used in specific clustered ways to create personal styles by individuals.

Students of Eckert’s are moving this view of variation and identity forward considerably. Sarah Benor (2001) investigated how the language of Orthodox Jews differs depending on their background and orientation to integrate into the Orthodox community. Her work is significant in two respects. First, it showed that identity is not just about the outward practices and styles of speakers, but that the internal orientations and ideologies of speakers can influence their use of language, and that the relationship between these orientations and language use are not necessarily linear. Second, she showed that adults, as they become integrated socially and ideologically into a new community with a different way of speaking (even if that new way is based on the rate of use of a linguistic variant), can change their speech to the new way of speaking. This finding suggests that speakers have much more control over how they speak than is often assumed. Benor’s work showed further the Eckertian view that most variables provide general meaning resources that acquire specific meanings in local contexts, since each analyzes essentially the same linguistic form, but show how its indexicality changes depending on the community and the individual speaker’s style.

I have been working with a more atomistic view than Eckert’s, but one that is consistent with her perspective. This view focuses on the performance of stances in interaction rather than personal styles. We can understand Eckert’s personal styles to be repertoires of stances; the variables used habitually by speakers to create these styles are primarily concerned with creating stances – relationships of the moment. In an analysis of the *-ing* variable used in a college all-male fraternity in the United States (Kiesling, 1998), I showed that the men who speak with a high rate of the ‘standard’ velar variant [-ŋ] in meetings are more likely than those whose rate is lower to be taking a stance at that point highlighting their structural power in the fraternity (through age or office-holding). These men also use grammatical forms that help them take an epistemic stance of certainty. Men who use the nonstandard coronal articulation [-n] in meetings tend to take a stance that highlights their connections to the aggregate of men (solidarity) or their ability to work hard for the fraternity. They also tend to use more profanity

and other nonstandard features, such as double negatives and *ain’t*. The point is that these differing rates of the variable shows the fraternity men to be taking particular stances at various points in specific interactions; it is not just that each man is from a certain class or ethnic background and uniformly reflects that in speech production. Moreover, one can explain why – in the context of the situation, the man’s personality, and cultural discourses and ideologies of masculinity, for example – he would take such a stance. This focus on stance moves us further toward an explanation of why speakers use the forms they do, and how these forms mean in interaction.

Such an interactionally local understanding of the indexicality of linguistic forms does not entail that wider cultural discourses, in this case norms of gender, are not also being indexed. In fact, we see here how the meanings of variation also exhibit the property of recursivity: the kinds of stances that the men take, sorting themselves out relationally, are all stances that index masculinity in their culture as well. In other words, they are able to ‘be men’ of one or another sort – not more or less male – while they are using *either* variant, because the dominant cultural discourses of masculinity include approved types that are both structurally or intellectually powerful (the standard users) and that are friendly or physically powerful (the nonstandard users). These cultural discourses are being recursively played out in the momentary stances the men take in the meetings.

In terms of method, in all of these directions of research, we find a curious marriage between the quantitative, objective, paradigm of variationist linguistics and the qualitative, subjectively-focused view of culture and interaction from sociocultural anthropology. One of the crucial ways that anthropology has informed the study of language and identity is in fact a focus on the speaker’s interpretive frameworks, to which we turn now.

Ethnographic Investigation of People’s Interpretive Frameworks

One of the strengths of LISA studies is the in-depth investigation of the speakers’ interpretive frameworks – how speakers themselves respond to language as reflective or constitutive of identity. This metapragmatic awareness, and its relationship to other indexicalities, is an important area of research in LISA. Silverstein (2001) proposed a classification that specifies under what kinds of conditions, and how, a linguistic form is likely to be accessible to metapragmatic awareness. While there is not space

to explain these principles here, Silverstein's work suggested that certain types of linguistic forms are more accessible resources for speakers to use to connect with identities.

Holland and Skinner (1987) took another approach, and argued that identities be understood as organized in the cultural models that speakers hold for the world. Such models are more specific than ideologies; they are in essence normative narratives of life trajectories or domains to which actual people are compared, especially in language. Holland and Skinner used the cultural model concept to understand how women at a southern U.S. college semantically organize the language they use to describe men.

Such interpretations of the relationship between language and identity are beginning to be articulated with traditional dialectological questions about how language relates to place. Johnstone (2004a, 2004b) suggested that a speaker's emplacement – that is, being culturally connected to place – is not simply another census identity, but one that is discursively negotiated like others. Speakers who live in the same geographical space take different orientations to it as a culturally meaningful place, and local dialect forms may function in various ways in everyday talk, in self-conscious performances, and in metalinguistic talk about the dialect, to index these orientations. The use of dialect forms to index orientation to place may help determine which forms are preserved and which are lost over time. This work indicates that even such taken-for-granted categories as place are ideologically organized by speakers, and that this ideological organization can affect the way speakers use language, and its meaning in terms of identities.

Language and Identity over Time

Future research in LISA is likely to focus on further understanding the ways in which indexicality works to create identities in interaction, from a number of perspectives. For one, the question of awareness is still a very open one, in which even what counts as awareness is not entirely clear. One can imagine a typology of awareness that can then be matched with Silverstein's accessibility hierarchy. Awareness may also be promoted by the media as well as face-to-face communication, and it is not clear the ways in which these modes of mediation differ for the creation of identity categories and indexicalities. Finally, the ways in which the use of these indexicalities construct and re-create identity categories, and especially relations of dominance among them, will continue to be a puzzle for some time.

Identity: Second Language

B Norton, University of British Columbia, Vancouver, BC, Canada

© 2006 Elsevier Ltd. All rights reserved.

Interest in second language identity in the field of applied linguistics is best understood in the context of a shift in the field from a predominantly psycholinguistic approach to second language acquisition (SLA) to include a greater focus on sociological and anthropological dimensions of second language learning, particularly with reference to sociocultural, poststructural, and critical theory. Researchers of second language identity have been interested not only in linguistic input and output in SLA, but in the relationship between the language learner and the larger social world. In particular, these researchers have examined the diverse social, historical, and cultural contexts in which language learning takes place and how learners negotiate and sometimes resist the diverse positions those contexts offer them.

Many researchers interested in second language identity are also interested in the extent to which relations of power within classrooms and communities promote or constrain the process of language learning. It is argued that the extent to which a learner speaks or is silent or writes, reads, or resists has much to do with the extent to which the learner is valued in any given institution or community. In this regard, social processes marked by inequities of gender, race, class, ethnicity, and sexual orientation may serve to position learners in ways that silence and exclude. At the same time, however, learners may resist marginalization through both covert and overt acts of resistance. What is of central interest to researchers of second language identity is that the very articulation of power, identity, and resistance is expressed in and through language. Language is thus more than a system of signs; it is social practice in which experiences are organized and identities negotiated.

After tracing the genesis of work in second language identity from the 1970s to the present day, this chapter outlines some of the major theoretical

influences on second language identity research. It then examines four trajectories of research that have much promise for the future: identity and investment, identity and imagined communities, identity categories and educational change, and identity and literacy.

The Historical Context

In the 1970s and 1980s, applied linguistics scholars interested in second language identity tended to draw distinctions between social identity and cultural identity. While 'social identity' was seen to reference the relationship between the individual language learner and the larger social world, as mediated through institutions such as families, schools, workplaces, social services, and law courts (e.g., Gumperz, 1982), 'cultural identity' referenced the relationship between an individual and members of a particular ethnic group (such as Mexican and Japanese) who share a common history, a common language, and similar ways of understanding the world (e.g., Valdes, 1986). In my own earlier work (Norton Peirce, 1995), I initially examined identity as a social construct as opposed to a cultural construct because I debated whether theories of cultural identity could do justice to the heterogeneity within the groups encountered and the dynamic and changing nature of identity observed in my research. As Atkinson (1999) has noted, past theories of cultural identity tended to essentialize and reify identities in problematic ways. In more recent years, however, the difference between social and cultural identity is seen to be theoretically more fluid, and the intersections between social and cultural identities are considered more significant than their differences. In this more recent second language research, identity is seen as socioculturally constructed, and scholars draw on both institutional and community practices to understand the conditions under which language learners speak, read, and write the target language.

A brief review of some of the articles published in the special issue of the *TESOL Quarterly* on Language and Identity exemplifies the increasingly interdisciplinary approach to second language identity research characteristic of the 1990s. I argued at the time that while the contributors framed their notions of identity in different terms, the similarities between the conceptions of identity were more marked than their differences (Norton, 1997). Thus Morgan (1997), for example, who was particularly interested in *social* identity, nevertheless explored the relationship between intonation and identity with reference to the dominant *cultural* practices of a particular group of Chinese immigrants in Canada. He did not,

however, reify these cultural practices, but sought to understand them in relation to the dynamics of ethnicity and gender. Schecter and Bayley (1997), who were particularly interested in *cultural* identity, nevertheless sought to understand their research with reference to larger *social* debates over the terms of Latino participation in American society, suggesting that social relations of class are important in understanding the relationship between language and identity. Duff and Uchida (1997), indeed, collapsed the distinctions between the social and the cultural by arguing for a sociocultural theory of identity in which identities and beliefs are co-constructed, negotiated, and transformed on a regular basis through language.

The diverse research covered in the 1997 *TESOL Quarterly* special issue, as well as special issues of *Linguistics and Education*, edited by Martin-Jones and Heller (1996), and *Language and Education*, edited by Sarangi and Baynham (1996), anticipated the wide range of research on second language identity characteristic of the early years of the 21st century. A number of monographs on the topic have appeared in catalogs and conferences (Day, 2002; Kanno, 2003; Miller, 2003; Norton, 2000; and Toohey, 2000); a growing body of research, common themes of which are discussed below, have been published in a wide variety of journals including *The Modern Language Journal* (Potowski, 2004), *TESOL Quarterly* (Lam, 2000; Maguire and Graves, 2001), and *Journal of Second Language Writing* (Hyland, 2002; Ramanathan and Atkinson, 1999); and there has been the establishment in 2002 of the award-winning *Journal of Language, Identity, and Education*, edited by Tom Ricento and Terrence Wiley, which has already published an exciting array of research on second language identity.

Current research on second language identity conceives of identity as dynamic, contradictory, and constantly changing across time and place. Indeed, a recurring theme throughout much of the research is that of 'transition.' Many of the participants in research projects on second language identity are undergoing significant changes in their lives, whether moving from one country to another (Kanno, 2003) or from one institution to the next (Harklau, 2000). Such transitions can be productive for language learning, providing learners with enhanced skills at negotiating bilingual identities; other transitions can be more problematic, as learners struggle to accommodate changing expectations in different institutional contexts. In such changing sets of circumstances, identities that might be seen as contradictory may in fact be constructed within contexts that are themselves sites of struggle (Cummins, 2000).

Theoretical Influences

A broad range of theorists have been influential in shaping current research on second language identity, most notable of whom are Bakhtin (1981, 1963/1984), Bourdieu (1977, 1979/1984), Weedon, and Lave and Wenger (1991). All of these theorists, while working within diverse disciplinary frameworks, are centrally concerned with both institutional and community practices that have an impact on learning.

Mikhail Bakhtin (1981, 1963/1984) takes the position that language needs to be investigated not as a set of idealized forms independent of their speakers or their speaking, but rather as situated utterances in which speakers, in dialogue with others, struggle to create meanings. For Bakhtin, the notion of the individual speaker is a fiction, as he sees all speakers constructing their utterances jointly on the basis of their interaction with listeners in both historical and contemporary, and both actual and assumed, communities. In this view, the appropriation of the words of others is a complex and conflictual process in which words are not neutral but express particular predispositions and value systems (see **Bakhtin, Mikhail Mikhailovich**).

Pierre Bourdieu (1977, 1979/1984), a contemporary French sociologist, focuses on the often unequal relationships between interlocutors and the importance of power in structuring speech. He suggests that the value ascribed to speech cannot be understood apart from the person who speaks and that the person who speaks cannot be understood apart from larger networks of social relationships. In this view, when a person speaks, the speaker wishes not only to be understood, but to be believed, obeyed, and respected. However, the speaker's ability to command the attention of the listener is unequally distributed because of the symbolic power relations between them. To redress the inequities between what Bourdieu calls 'legitimate' and 'illegitimate' speakers, he argues that an expanded definition of competence should include the "right to speech" or "the power to impose reception" (1977: 648).

The work of Christine Weedon, like that of Bakhtin and Bourdieu, is centrally concerned with the conditions under which people speak, within both institutional and community contexts. Like other poststructuralist theorists who inform her work, Weedon foregrounds the central role of language in her analysis of the relationship between the individual and the social, arguing that language not only defines institutional practices, but also serves to construct our sense of ourselves and our "subjectivity" (Weedon, 1987: 21). Weedon notes that the terms *subject* and *subjectivity* signify a different conception of the individual than that associated with

humanist conceptions of the individual dominant in Western philosophy. While humanist conceptions of the individual presuppose that every person has an essential, unique, fixed, and coherent 'core,' poststructuralism depicts the individual (i.e., the subject) as diverse, contradictory, dynamic, and changing over historical time and social space.

A shift from seeing learners as individual language producers to seeing them as members of social and historically constituted communities is of much interest to anthropologists Jean Lave and Etienne Wenger. Lave and Wenger (1991) argue that what they call "situated learning" is an integral and inseparable part of social practice, as newcomers are mentored into the performance of community practices (see **Communities of Practice**). Their notion "legitimate peripheral participation" represents their view that communities are composed of participants who differentially engage with the practices of their community and that conditions vary with regard to ease of access to expertise, to opportunities for practice, to consequences for error in practice, and so on. From this perspective, then, educational research might focus not so much on assessing individual 'uptake' of particular knowledge or skills, but on the social structures in particular communities and on the variety of positionings available for learners to occupy in those communities.

Rather than seeing language learning as a gradual individual process of internalizing a neutral set of rules, structures, and vocabulary of a standard language, the work of Bakhtin, Bourdieu, Weedon, and Lave and Wenger offers applied linguists ways to think differently about language learning. Such theory suggests that second language learners need to struggle to appropriate the voices of others; they need to learn to command the attention of their listeners; they need to negotiate language as a system and as a social practice; and they need to understand the practices of the communities with which they interact. Drawing on such theory, becoming a 'good' language learner is seen to be a much more complicated process than earlier research had suggested (Norton and Toohey, 2001).

Research Trajectories

Research on second language identity has taken a number of interesting directions that hold much promise. The four trajectories I wish to examine address research on identity and investment, identity and imagined communities, identity categories and educational change, and identity and literacy.

Identity and Investment

In my research with immigrant women in Canada (Norton, 2000; Norton Peirce, 1995), I observed that

existing theories of motivation in the field of SLA were not consistent with the findings from my research. Most theories at the time assumed motivation was a character trait of the individual language learner and that learners who failed to learn the target language were not sufficiently committed to the learning process. Such theories did not do justice to the identities and experiences of the language learners in my research. For this reason, I made the case that the notion of 'investment' might help to extend notions of motivation in the field of SLA. The notion of investment, inspired by the work of Bourdieu, signals the socially and historically constructed relationship of learners to the target language and their often ambivalent desire to learn and practice it. If learners 'invest' in the target language, they do so with the understanding that they will acquire a wider range of symbolic and material resources, which will in turn increase the value of their cultural capital. Unlike notions of instrumental motivation, which conceive of the language learner as having a unitary, fixed, and ahistorical 'personality,' the notion of investment conceives of the language learner as having a complex identity, changing across time and space, and reproduced in social interaction. An investment in the target language is best understood as an investment in the learner's own identity.

The notion of investment has sparked considerable interest in the field of applied linguistics (see Pittaway, 2004). McKay and Wong (1996), for example, have drawn on this concept to explain the English language development of four Mandarin-speaking students in Grades 7 and 8 in a California school. They note that the needs, desires, and negotiations of students are not simply distractions or deviations from an ideal language learning situation; on the contrary, they must be regarded as constituting "the very fabric of students' lives and as determining their investment in learning the target language" (McKay and Wong, 1996: 603). Angelil-Carter (1997) found the concept useful in understanding the language development of an English language learner in South Africa, noting how the student's investment in prior discourses impacted on his acquisition of written academic discourses. Skilton-Sylvester (2002), drawing on her research with four Cambodian women in adult ESL classes in the United States, has argued that traditional views of adult motivation and participation are limited because they do not address the complex lives of adult learners or their investment in learning English. Her findings suggest that an understanding of a woman's domestic and professional identities is necessary to explain the investment in particular adult ESL programs. Potowski (2004) uses the notion of investment to explain students' use of Spanish in a dual Spanish/English immersion program

in the United States. She notes that no matter how well-run a language program is, unless a learner's investment in the target language is consistent with the goals of the program, target language growth may not meet expectations. Potowski makes the case that the notion of investment makes an important contribution not only to the study of SLA, but to research on heritage language maintenance.

Identity and Imagined Communities

An extension of interest in identity and investment concerns the imagined communities that language learners aspire to when they learn a new language. In Norton (2001), I drew on my research with two adult immigrant language learners to argue that while the learners were initially actively engaged in classroom practices, the realm of their desired community extended beyond the four walls of the classroom. This imagined community was not accessible to their respective teachers, who, unwittingly, alienated the two language learners who then withdrew from the language classroom. The work of Lave and Wenger (1991) and Wenger (1998) helped me to make sense of this data. In many second language classrooms, all of the members of the classroom community, apart from the teacher, are newcomers to a set of language practices and to a community that includes those language practices in its activities. The question that arises then is what community practices do these learners seek to learn? What, indeed, constitutes 'the community' for them?

For many language learners, the community is one of the imagination – a desired community that offers possibilities for an enhanced range of identity options in the future. The community may also be, to some extent, a reconstruction of past communities and historically constituted relationships. In essence, an imagined community assumes an imagined identity, and a learner's investment in the target language must be understood within this context. Learners have different investments in particular members of the target language community, and the people in whom learners have the greatest investment may be the very people who represent or provide access to the imagined community of a given learner. Of particular interest to the language educator is the extent to which such investments are productive for learner engagement in both the classroom and the wider target language community. Such questions have been taken up more extensively in a coedited special issue of the *Journal of Language, Identity, and Education* on Imagined Communities and Educational Possibilities (Kanno and Norton, 2003) in which Adrian Blackledge, Diane Dagenais, Farah Kamal, Yasuko Kanno, Bonny Norton, Aneta Pavlenko, and Sandra Silberstein

explore the imagined communities of specific groups of learners in Canada, Japan, Pakistan, the United Kingdom, and the United States.

Identity Categories and Educational Change

While much research on second language identity explores the multiple and intersecting dimensions of learners' identities, there is a growing body of research that seeks to investigate the ways in which particular relations of race, gender, class, and sexual orientation may have an impact on the language learning process (Norton and Toohey, 2004). Innovative research that addresses these issues does not regard such identity categories as variables, but rather as sets of relationships that are socially and historically constructed within particular relations of power. Ibrahim's (1999) research with a group of French-speaking continental African students in a Franco-Ontarian High School in Canada explores the impact on language learning of 'becoming black.' He argues that the students' linguistic styles, and in particular their use of Black Stylized English, was a direct outcome of being imagined and constructed as Black by hegemonic discourses and groups. From a slightly different perspective, Taylor's (2004) research in an anti-discrimination camp in Toronto, Canada, argues for the need to understand language learning through the lens of what she calls *racialized gender*. The stories of Hue, a Vietnamese girl, and Khatra, a Somali girl, are particularly powerful in this regard, supporting the view held by Kubota (2004) that a color-blind conception of multiculturalism does not do justice to the challenges faced by language learners of diverse races and ethnicities.

Similarly, the work of scholars such as Ehrlich (1997) and Pavlenko (2004) is particularly insightful with regard to intersections of gender and language learning. Their conception of gender, which extends beyond female-male divides, is understood to be a system of social relationships and discursive practices that may lead to systemic inequality among particular groups of learners, including women, minorities, elderly, and disabled. Pavlenko, for example, argues for the need to understand the intersections between gender and other forms of oppression, noting that both girls and boys who are silenced in the language classroom are more likely those from the working class. In a similar spirit, Nelson (2004) explores the extent to which sexual orientation might be an important identity category in the second language classroom. Of central interest is the way in which a teacher can create a supportive environment for learners who might be gay, lesbian, or transgendered. Interest in identity categories and language learning is gaining

momentum. A special issue of the *TESOL Quarterly* on Gender and Language Education, edited in 2004 by Kathy Davis and Ellen Skilton-Sylvester as well as an edited volume *Gender and English Language Learners* (Norton and Pavlenko, 2004) are available.

Identity and Literacy

Researchers of second language identity have become interested not only in the conditions under which language learners speak, but in the extent to which identities and investments structure their engagement with *texts*. There is growing recognition that when a second language learner reads or writes a text, both the comprehension and construction of the text is mediated by the learner's investment in the activity and the learner's sociocultural identity. By way of example, Norton Peirce and Stein (1995) demonstrate how the meaning of a South African reading comprehension text shifted when the social conditions under which it was read changed. They argue that the changing social occasions created different kinds of investments on the part of the students, and as the students' identities shifted from compliance to resistance, so did their interpretation of the text. Student resistance is also a theme in Canagarajah's (2004) literacy research with Tamil students in Sri Lanka and African American students in the United States, in which he demonstrates how students learning a second language or dialect sometimes engage in clandestine literacy activities to resist unfavorable identities imposed on them.

Much emerging research on literacy and second language identity also addresses the impact of literacy practices on relationships beyond the classroom. Lam (2000), for example, studied the Internet correspondence of a Chinese immigrant teenager in the United States who entered into transnational communication with a group of peers. She demonstrates how this experience of what she calls *textual identity* related to the student's developing identity in the use of English. The research of Kramsch and Thorne (2002) indicates, however, that not all transnational Internet communication leads to positive identity outcomes. In their study of the synchronous and asynchronous communication between American learners of French in the United States and French learners of English in France, they found that students had little understanding of the larger cultural framework within which each party was operating, leading to problematic digital exchanges. Ramanathan and Atkinson (1999), indeed, make the case that there is much need for cross-cultural writing research to better inform both teachers and students of the sociocultural knowledge of student writers from diverse regions of the world.

Scholars such as Luke (2004), Kress (1993), and Ivanič (1997) have influenced much research on the relationship between literacy and second language identity. While Luke's work has focused on the contribution of critical literacy to second language education and Kress's on the conception of text as a socially and historically constituted genre, Ivanič has explored the notion of writer identity, making the case that writers' identities are constructed in the possibilities for self-hood available in the sociocultural contexts of writing. Ivanič's distinctions between the "autobiographical self," the "discoursal self," and the "authorial self" have been useful in writing research with both young second language learners (Maguire and Graves, 2001) and college-level students (Hyland, 2002; Starfield, 2002).

Conclusion

Research on second language identity has struck a chord in the field of applied linguistics, opening up multiple avenues for research on every aspect of the field. While this chapter has focused on the identity of the second language learner, there is now increasing interest in the identity of the second language teacher (Johnston, 2002; Lin, 2004), the second language teacher educator (Goldstein, 2003; Pennycook, 2004), and the second language researcher (Hawkins, 2004; Leung *et al.*, 2004). If we take seriously the argument that the identity of the second language learner is not a personality variable but a socially and historically constructed relationship to both institutional and community practices, then it follows that teachers, researchers, administrators, testers, and policy makers are all implicated in the range of identities available to the second language learner. There is every indication that the interest in second language identity will grow in momentum, enriching existing trajectories of research and forging new, exciting directions.

Implicature

J Meibauer, Universität Mainz, Mainz, Germany

© 2006 Elsevier Ltd. All rights reserved.

The Basic Notions

The term ‘*implicature*’ goes back to the philosopher Paul Grice, as laid down in his seminal article ‘Logic and Conversation’ (Grice, 1989), which is the published version of a part of his William James lectures held in 1967 at Harvard University (see Grice, Herbert Paul). In Grice’s approach, both ‘what is implicated’ and ‘what is said’ are part of speaker meaning. ‘What is said’ is that part of meaning that is determined by truth-conditional semantics, while ‘what is implicated’ is that part of meaning that cannot be captured by truth conditions and therefore belongs to pragmatics. Several types of implicature are distinguished. Figure 1 shows the Gricean typology of speaker meaning (cf. Levinson, 1983: 131).

The most widely accepted type of implicature is the *conversational implicature*. According to Grice, it comes in two ways, generalized conversational implicature (GCI) and particularized conversational implicature (PCI). The following example from Levinson (2000: 16–17) illustrates this distinction:

- Context, 1** Speaker A: What time is it?
 Speaker B: Some of the guests are already leaving.
 PCI: ‘It must be late.’
 GCI: ‘Not all of the guests are already leaving.’
- Context, 2** Speaker A: Where’s John?
 Speaker B: Some of the guests are already leaving.
 PCI: ‘Perhaps John has already left.’
 GCI: ‘Not all of the guests are already leaving.’

Because the implicature (‘... not all ...’) triggered by *some* arises in both contexts, it is relatively context-independent. Relative context-independence is the most prominent property of GCIs. In addition, GCIs are normally, or even consistently, associated with certain linguistic forms. For example, if someone

Figure 1 Gricean typology of speaker meaning.

utters *Peter is meeting a woman this evening* it is, because of the indefinite article, standardly implicated that the woman is not his wife, close relative, etc. (cf. Grice, 1989: 37; Hawkins, 1991). In contrast to GCIs, PCIs are highly context-dependent, and they are not consistently associated with any linguistic form.

The distinction between conversational implicatures and *conventional implicatures* draws on the observation that in coordinations like *Anna is rich but she is happy*, the truth conditions are just the truth conditions of the coordination *Anna is rich and she is happy*, with the exception of the contrastive meaning of *but*. This meaning is not truth-functional, and it is not context-dependent either; hence, there is some motivation for assuming the category of conventional implicature.

Note that there may be further types of implicature, e.g., implicatures of politeness or style that are neither conventional nor conversational (cf. Leech, 1983; Brown and Levinson, 1987).

Conversational implicatures come about by the *exploitation* (apparent flouting) or *observation* of the *cooperative principle* (CP) and a set of maxims (Grice, 1989) (see **Cooperative Principle; Maxims and Flouting**):

Cooperative Principle

Make your conversational contribution such as is required, at the stage at which it occurs, by the accepted purpose or direction of the talk exchange in which you are engaged.

Maxim of Quantity

1. Make your contribution as informative as is required (for the current purposes of exchange).
2. Do not make your contribution more informative than is required.

Maxim of Quality

Try to make your contribution one that is true.

1. Do not say what you believe to be false.
2. Do not say that for which you lack adequate evidence.

Maxim of Relevance

Be relevant.

Maxim of Manner

Be perspicuous.

1. Avoid obscurity of expression.
2. Avoid ambiguity.
3. Be brief (avoid unnecessary prolixity).
4. Be orderly.

These maxims and submaxims are conceived as rules of rational behavior, not as ethical norms. They figure prominently in the derivation of an implicature.

The basic idea of such a derivation is best illustrated with a simple dialogue. Imagine that I ask my colleague *Is Markus there?* and she answers *There is a pink Porsche behind the library building*. Understood literally, such an answer does not make any sense. However, as I assume that my colleague is cooperative, and remembering that Markus drives a pink Porsche, I can figure out that Markus is in the library. In working out this information, I have made use of the assumption that my colleague's answer has been relevant with regard to my question. Thus, conversational implicatures display the property of *calculability*. A general scheme for the working out of a conversational implicature is given by Grice (1989: 30–31):

A man who, by (in, when) saying (or making as if to say) that *p* has implicated that *q*, may be said to have conversationally implicated that *q*, provided that (1) he is to be presumed to be observing the conversational maxims, or at least the Cooperative Principle; (2) the supposition that he is aware that, or thinks that, *q* is required in order to make his saying or making as if to say *p* (or doing so in *those* terms) consistent with this presumption; and (3) the speaker thinks (and would expect the hearer to think that the speaker thinks) that it is within the competence of the hearer to work out, or grasp intuitively, that the supposition in (2) is required.

Table 1 lists some of the most typical cases covered by the CP and the maxims. Examples for each case are given below the table. For further classical examples, see Grice (1989) and Levinson (1983). In what follows, '+>' stands for 'implicates conversationally':

- (1) War is war. +> 'There is nothing one can do about it.'
- (2) Some men were drunk. +> 'Not all of them were drunk.'
- (3a) He is a fine friend. +> 'He is not a fine friend.'
- (3b) You are the cream in my coffee. +> 'You are my best friend.'
- (4) There is life on Mars. +> 'Speaker believes that there is life on Mars.'

Table 1 Typical cases of implicature

Maxims	Exploitation	Observation
Quantity	Tautology (1)	Scalar implicature (2)
Quality	Irony, metaphor, sarcasm (3)	Belief implicature in assertions (4)
Relevance	Implicatures due to thematic switch (5)	Bridging (6)
Manner	Implicatures due to obscurity, etc. (7)	Conjunction buttressing (8)

- (5) Speaker A: I'm out of petrol.
Speaker B: There is a garage round the corner.
+> 'The garage is open.'
- (6) Speaker A: Look, that old spinster over there!
Speaker B: Nice weather today, isn't it? +> 'No comment.'
- (7) She produced a series of noises that resembled "Si, mi chiamano Mimi". +> 'Her singing was a complete disaster.'
- (8) Anna went to the shop and bought jeans. +> 'She bought the jeans in the shop.'

For further illustration of the exploitation/observation dichotomy, look at (1) and (8). As to (1), tautological utterances are always true, which amounts to their being fundamentally uninformative. There is no situation where a speaker wants to tell someone that something is identical with itself. Thus, it seems that the utterer of (1) has violated the first maxim of Quality. Gricean reasoning then leads the hearer to the insight that this violation was only apparent (cf. Autenrieth, 1997). In (8), we have a simple conjunction of two sentences. If the meaning of *and* were to be the same as the meaning of the logical operator, it could not be explained that there is an additional meaning 'and then.' Grice's view is that we may identify the semantic meaning of *and* with the pure connecting operation known from logic as long as we are able to derive the additional meaning from the maxims. The observation of the fourth maxim of Manner, "Be orderly!", will do this job (cf. Posner, 1980). Both observation and exploitation are in line with the general pattern for working out an implicature.

Besides the property of calculability, conversational implicatures display the properties of variability and cancellability. *Variability* means that there are contexts where the speaker utters the same utterance, but the respective implicature does not arise. Thus, the implicature is dependent on the specific context in which it arises. (This does not exclude the notion of relative context-independency in the case of GCIs.) *Cancellability* (or defeasibility) means that it is possible to withdraw an implicature within the situation of utterance without any contradiction. For example, it is possible to utter *Some men were drunk, indeed all*. Reversely, conversational implicatures should be *reinforceable*, as Sadock (1978) proposed. Thus, it is possible to conjoin the content of an implicature with the utterance that triggers that implicature, as in *Some of the girls were reading books but not all*.

Conventional implicatures are neither calculable, nor variable, nor cancellable. However, they are said to be detachable, i.e., if the elements that trigger them are replaced, the respective implicature does not arise.

By contrast, conversational implicatures are *non-detachable*, i.e., if there is an expression X' that shares meaning with expression X that triggers the implicature, the same implicature should arise. For example, if *She is very beautiful* gives rise to an ironical implicature, then *She is a real beauty* should have the same effect (Sadock, 1978: 287). (An obvious exception to this are Manner implicatures.)

For further illustration, consider focus particles like *even*. An utterance such as *Even JOHN drives a Porsche* has the same truth conditions as the corresponding utterance without the focus particle, i.e., *John drives a Porsche*. The additional meaning of the type 'John is the least likely to drive a Porsche,' being related to a contextually given set of other individuals (e.g., Gustav, Bettina, Markus...), may be considered as a conventional implicature (cf. König, 1991), because this meaning appears to be neither truth-conditional nor context-dependent. Moreover, if *even* is replaced by another focus particle, the respective implicature is not triggered. However, if the conventional implicature is bound to the specific lexical item *even*, and for this reason is detachable, then the implicature seems to be part of the literal meaning of this lexical item. Therefore, it is difficult to distinguish between conventional implicatures on the one hand and entailments (belonging to the 'what is said') on the other hand. For this and other reasons, some researchers do not accept that there is a category of conventional implicature (cf. Bach, 1999; for a logical approach, see Potts, 2005).

Beyond Grice

The reception of the Gricean framework has been largely dominated by the wish to develop a more systematic architecture of maxims. Moreover, the Cooperative Principle has been on trial, as other aspects (e.g., logical, anthropological, cognitive, etc.) became more attractive. The prevailing tendency has been to reduce the set of maxims proposed by Grice. Three major reductive approaches have been

developed: (a) the tri-heuristic approach by Levinson (2000), (b) the dual principle approach by Horn (1984), and (c) the monopricipled approach by Sperber and Wilson (1995) and Carston (2002). These approaches are outlined in the following sections. It should be mentioned, however, that there are other important approaches that elaborate on the Gricean framework, e.g., Gazdar (1979) or Atlas (2005), as well as radical criticisms such as Davis (1998). For useful surveys, see Levinson (1983: Ch. 3) and Rolf (1994).

Presumptive Meanings: Levinson's Theory of Generalized Conversational Implicature

Levinson develops his revision of Grice's maxims from three heuristics that follow from the anthropological need to overcome the "fundamental bottleneck in the efficiency of human communication, occasioned no doubt by absolute physiological constraints on the articulators" (Levinson, 2000: 28). Accordingly, Grice's rationalistic CP plays no role. The heuristics are (Levinson, 2000: 31–33):

Levinson's Heuristics

Heuristic 1: What isn't said, isn't.

Heuristic 2: What is simply described, is stereotypically exemplified.

Heuristic 3: What's said in an abnormal way, isn't normal; or Marked message indicates marked situation.

Heuristics 1 corresponds to Levinson's Q-principle (see maxim of Quantity 1 in Grice's framework), Heuristics 2 to Levinson's I-principle (Grice's maxim of Quantity 2), and Heuristics 3 to Levinson's M-principle (Grice's maxim of Manner 1 and 3). These three principles are said to derive GCIs. For the correspondences to Grice, and a typical example, see Table 2.

Where inconsistent implicatures arise, they are "systematically resolved by an ordered set of priorities" (Levinson, 2000: 39), among them $Q > M > I$, where ' $>$ ' is understood as 'defeats inconsistency.' Levinson (2000: 153–164) gives some examples for $Q > I$, $Q > M$, and $M > I$. An example for $Q > M$ is

Table 2 Correspondences between Levinson's Heuristics and Principles, and Grice's Maxims

Heuristics	Principles	Grice's Maxims	Example
Heuristic 1	Q-Principle	Quantity, 1	Q-Implicature: (a) Some colleagues were drunk. $+>$ 'Not all of them were drunk.' (scalar implicature) (b) The doctor believes that the patient will not recover. $+>$ 'The doctor may or may not know that the patient will not recover.' (clausal implicature)
Heuristic 2	I-Principle	Quantity, 2	I-Implicature: Anna turned the switch and the motor started. $+>$ 'Anna turned the switch and then/therefore the motor started.' (conjunction buttressing)
Heuristic 3	M-Principle	Manner, 1 and 3	M-Implicature: Bill caused the car to stop. (vs. Bill stopped the car.) $+>$ 'He did this indirectly, not in the normal way, e.g., by use of the emergency brake.' (periphrasis)

It's not unlikely that Giant Stride will win the Derby, and indeed I think it is likely. Here, as Levinson (2000: 160) points out, the first conjunct gives rise to the M-based implicature 'less than fully likely,' because of the double negative *not unlikely*, while the second conjunct triggers the Q-based implicature 'it is possible it is likely,' because of the use of *think*, which does not entail the complement clause. In this case, the Q-implicature of the second conjunct defeats the M-implicature of the first. (However, as Traugott, 2004: 11 observes, *indeed* may serve as a M-implicature cancelling device.)

The Q-principle is defined as follows (Levinson, 2000: 76):

Q-principle

Speaker's maxim: Do not provide a statement that is informationally weaker than your knowledge of the world allows, unless providing an informationally stronger statement would contravene the I-principle. Specifically, select the informationally strongest paradigmatic alternate that is consistent with the facts.

Recipient's corollary: Take it that the speaker made the strongest statement consistent with what he knows, and therefore that:

- a. if the speaker asserts $A(W)$, where A is a sentence frame and W an informationally weaker expression than S , and the contrastive expressions $\langle S, W \rangle$ form a Horn scale (in the prototype case such that $A(S)$ entails $A(W)$), then one can infer that the speaker knows that the stronger statement $A(S)$ (with S substituted for W) would be false [...]
- b. if the speaker asserted $A(W)$ and $A(W)$ fails to entail an embedded sentence Q , which a stronger statement $A(S)$ would entail, and $\{S, W\}$ form a contrast set, then one can infer that the speaker does not know whether Q obtains or not (i.e., $\{P(Q), P \sim (Q)\}$ read as 'it is epistemically possible that Q and epistemically possible that not- Q '

The I-Principle mentioned in the Speaker's maxim requires that a speaker should not be more informative than necessary (see below). Wherever it is possible, the speaker should build on stereotypical assumptions. In the Recipient's corollary, two cases are distinguished, namely scalar implicature, involving Horn scales (named after Laurence Horn, see the next section) and clausal implicature, involving contrast sets.

In the case of *scalar implicatures*, we need a *Horn scale*: given a scale $\langle q, p \rangle$ with p as an informationally weak and q as an informationally strong element, the assertion of p implicates the negation of q . In such cases, the speaker is supposed to be as informative as possible, thus observing the Q-principle (or the maxim of Quantity). Therefore, the speaker could not say more than he actually did, and this means

that the stronger statement does not hold. A classical example is the utterance $p = \text{'Some colleagues were drunk'}$ implicating $q = \text{'Not all of them were drunk'}$. In the case of *clausal implicatures*, we need *contrast sets*. Let $\{\text{know, believe}\}$ be a contrast set. Then $p = \text{'The doctor believes that the patient will not recover'}$ implicates $q_1 = \text{'The doctor may or may not know that the patient will not recover'}$ (Levinson, 2000: 110). The crucial point is that clausal implicatures indicate epistemic uncertainty about the truth of the embedded sentence. Note that, because $\langle \text{know, believe} \rangle$ also form a Horn scale, there is a scalar implicature as well: in this case p implicates $q_2 = \text{'The doctor does not know that the patient will not recover.'}$

Well-known Horn scales include the quantifiers $\langle \text{all, most, many, some} \rangle$, connectives $\langle \text{and, or} \rangle$, modals $\langle \text{necessarily, possibly} \rangle$, $\langle \text{must, should, may} \rangle$, adverbs $\langle \text{always, often, sometimes} \rangle$, degree adjectives $\langle \text{hot, warm} \rangle$, and verbs $\langle \text{know, believe} \rangle$, $\langle \text{love, like} \rangle$. Contrast sets include verbal doublets like $\{\text{know, believe}\}$, $\{\text{realize, think}\}$, $\{\text{reveal, claim}\}$, $\{\text{predict, foresee}\}$, and others (cf. Levinson, 2000: 111).

Now consider the I-principle (Levinson, 2000: 114–115):

I-Principle

Speaker's maxim: the maxim of Minimization. 'Say as little as necessary'; that is, produce the minimal linguistic information sufficient to achieve your communicational ends (bearing Q in mind).

Recipient's corollary: the Enrichment Rule. Amplify the informational content of the speaker's utterance by finding the most *specific* interpretation, up to what you judge to be the speaker's m-intended [= meaning-intended] point, unless the speaker has broken the maxim of Minimization by using a marked or prolix expression.

Specifically:

- a. Assume the richest temporal, causal and referential connections between described situations or events, consistent with what is taken for granted.
- b. Assume that stereotypical relations obtain between referents or events, unless this is inconsistent with (a).
- c. Avoid interpretations that multiply entities referred to (assume referential parsimony); specifically, prefer coreferential readings of reduced NPs (pronouns and zeros).
- d. Assume the existence or actuality of what a sentence is about (if that is consistent with what is taken for granted).

This principle is said to cover a whole range of implicatures: conditional perfection (9), conjunction buttressing (10), bridging (11), inference to stereotype (12), negative strengthening (13), NEG-raising (14), preferred local coreference (15), the mirror

maxim (16), specialization of spatial terms (17), and possessive interpretations (18) (cf. Levinson, 2000: 117–118).

- (9) If you mow the lawn, I'll give you five dollars.
+> 'If you don't mow the lawn, I will not give you five dollars.'
- (10) Bettina wrote an encyclopedia and sold the rights to Elsevier. +> 'Bettina wrote an encyclopedia and then sold the rights to Elsevier.'
- (11) Gustav unpacked the picnic. The beer was warm. +> 'The beer was part of the picnic.'
- (12) Markus said 'Hello' to the secretary and then he smiled. +> 'Markus said "Hello" to the female secretary and then Markus smiled.'
- (13) I don't like Alice. +> 'I positively dislike Alice.'
- (14) I don't think he is reliable. +> 'I think he is not reliable.'
- (15) John came in and he sat down. +> 'John_i came in and he_i sat down.'
- (16) Harry and Sue bought a piano. +> 'They bought it together, not one each.'
- (17) The nail is in the wood. +> 'The nail is buried in the wood.'
- (18) Wendy's children +> 'those to whom she is parent'; Wendy's house +> 'the one she lives in'; 'Wendy's responsibility' +> the one falling on her; Wendy's theory +> 'the one she originated'

The M-principle is defined as follows (Levinson, 2000: 136–137):

M-principle

Speaker's maxim: Indicate an abnormal, nonstereotypical situation by using marked expressions that contrast with those you would use to describe the corresponding normal, stereotypical situation.

Recipient's corollary: What is said in an abnormal way indicates an abnormal situation, or marked messages indicate marked situations, specifically:

Where *S* has said *p*, containing a marked expression *M*, and there is an unmarked alternate expression *U*, with the same denotation *D*, which the speaker might have employed in the same sentence-frame instead, then where *U* would have I-implicated the stereotypical or more specific subset *d* of *D*, the marked expression *M* will implicate the complement of the denotation *d*, namely \bar{d} of *D*.

The M-principle is supposed to cover a range of cases, among them lexical doublets (19) and rival word formations (20), nominal compounds (21), litotes (22), certain genitive (23) and zero morph

constructions (24), periphrasis (25), and repetition (26) (cf. Levinson, 2000: 138–153).

- (19) She was reading a tome [vs. book]. +> 'She was reading some massive, weighty volume.'
- (20) Ich nehme den Flieger [vs. das Flugzeug].
(= I take the plane [vs. the airplane]) +>
'Fliegen ist nichts Besonderes für mich.'
(= 'Flying is quite normal for me.')
- (21) This is a box for matches (vs. matchbox). +>
'This is a (nonprototypical) box specially made for containing matches.'
- (22) It took a not inconsiderable effort. +> 'It took a close-to-considerable effort.'
- (23) the picture of the child (vs. the child's picture)
+> 'the picture depicts the child'
- (24) She went to the school/the church/the university
(vs. to school, to church, to university, etc.)
+> 'She went to the place but not necessarily to do the associated stereotypical activity.'
- (25) Bill caused the car to stop. (vs. Bill stopped the car.) +> 'He did this indirectly, not in the normal way (e.g., by using the emergency brake).'
- (26) He went to bed and slept and slept. +> 'He slept longer than usual.'

Note that only the first ('Avoid obscurity of expression') and the third ('Be brief (avoid unnecessary prolixity)') submaxims of the Gricean maxims of Manner survive in Levinson's M-principle. Levinson views the second submaxim ('Avoid ambiguity') in connection with 'generality narrowing', which is subsumed under the Q-principle (Levinson, 2000: 135). The fourth submaxim ('Be orderly') is not needed any more, because the notorious cases of 'conjunction buttressing' fall under the I-principle in Levinson's framework. Moreover, Levinson (2000: 135) notes the general cognitive status of this general semiotic principle of linearization, and he questions its status as a maxim.

It seems that many of the cases in (19)–(26) may be explained in terms of the Q- or I-principle; in other cases, it is not at all clear that we have the same denotation, as required in the Recipient's corollary of the M-principle, thus throwing into doubt whether a separate M-principle is really needed. By comparison, Horn's (1984) approach (sketched in the next section) has no separate maxim/principle of Manner. For further discussion, see Meibauer (1997) and Traugott (2004).

Obviously, the maxim of Quality and the maxim of Relevance are not maxims that figure in the derivation of GCIs. The only comment on the

maxim of Quality Levinson gives is that this maxim “plays only a background role” in the derivation of GCIs; maybe he has the sincerity conditions for assertive acts in mind (Levinson, 2000: 74). Note that Grice (1989: 34) needed the maxim of Quality to derive the implicatures in the cases of irony, metaphor, and sarcasm (see **Irony**). In contrast, Levinson argues that irony and sarcasm are cases of PCIs (Levinson, 2000: 386, Fn. 2), a claim that seems somewhat premature at least when considering cases of conventional irony and sarcasm. The maxim of Relevance is a maxim that, according to Levinson (2000: 74), derives only PCIs. However, this maxim seems to play a role when it comes to disambiguation and ‘ellipsis unpacking’ (Levinson, 2000: 174, 183) (see **Relevance Theory**).

In addition to the revision of the Gricean maxims just outlined, Levinson sketches a radical revision of the widely accepted Gricean view of the interaction of grammar and pragmatics according to which in language production, conversational implicatures are supposed to operate on, and follow the semantic representation of, the said (Levinson, 2000: 173). Levinson finds this view basically wrong:

Grice’s account makes implicature dependent on a prior determination of ‘the said.’ The said in turn depends on disambiguation, indexical resolution, reference fixing, not to mention ellipsis unpacking and generality narrowing. But each of these processes, which are prerequisites to determining the proposition expressed, may themselves depend crucially on processes that look undistinguishable from implicatures. Thus, what is said seems both to determine and to be determined by implicature. Let us call this *Grice’s circle*. (Levinson, 2000: 186)

According to Levinson, there are at least five phenomena that show the influence of GCIs on sentence meaning (Levinson, 2000: 172–187). First, GCIs (of the scalar type) are involved in the disambiguation of ambiguous constructions like *some cats and dogs*, for only the bracketing *[[some cats] and dogs]*, with the appropriate implicature ‘some but not all cats, and dogs in general,’ is appropriate in the sentence *He’s an indiscriminate dog-lover; he likes some cats and dogs*. Second, the resolution of indexicals is dependent on the calculation of GCIs, e.g., *The meeting is on Thursday*. +> ‘not tomorrow’ (when tomorrow is Thursday). Third, reference identification often requires GCIs, e.g., *John came in and the man sat down*. +> ‘The man was not identical to John.’ Fourth, in ellipsis unpacking, as in simple dialogues like *Who came? – John <came>*, the missing information is constructed on the basis of Relevance and I-Implicature. Finally, there is the case of

generality narrowing, e.g., if someone utters *I’ve eaten breakfast* +> ‘I’ve eaten breakfast [this morning]’ where the Q-principle is activated.

In order to resolve the dilemma of Grice’s circle, i.e., to account for ‘pragmatic intrusion,’ Levinson proposes an alternative model (Levinson, 2000: 188). This model contains three pragmatic components, namely Indexical Pragmatics, Gricean Pragmatics 1, and Gricean Pragmatics 2, and two semantic components, namely Compositional Semantics and Semantic Interpretation (model-theoretic interpretation). The output of Compositional Semantics and Indexical Pragmatics is input for Gricean Pragmatics 1. The output of Gricean Pragmatics 1 is input for Semantic Interpretation, and its output (‘sentence meaning, proposition expressed’) is input for Gricean Pragmatics 2, whose output is ‘speaker meaning, proposition meant by the speaker.’

Whereas Indexical Pragmatics and Gricean Pragmatics 1 are presemantic pragmatic components, Gricean Pragmatics 2 is a postsemantic pragmatic component. It seems that Gricean Pragmatics 2 deals with PCIs (‘indirection, irony and tropes, etc.’) whereas Gricean Pragmatics 1 deals with GCIs (‘disambiguation, fixing reference, generality-narrowing, etc.’). At the heart of Levinson’s approach is his analysis of GCIs, precisely because it is here that arguments for this new model of the semantics-pragmatics interaction may be found.

Division of Pragmatic Labor: Horn’s Q- and R-Principles

Central to Horn’s approach to implicature is the insight that implicatures have to do with “regulating the economy of linguistic information” (Horn, 2004: 13). In contrast to Levinson, Horn (1984) assumes only two principles, the Q-principle and the R-principle:

Q-principle

Make your contribution sufficient: Say as much as you can (given R).

(Lower-bounding principle, inducing upper-bounding implicatures)

R-principle

Make your contribution necessary: Say no more than you must (given Q).

(Upper-bounding principle, inducing lower-bounding implicatures)

The Q-principle collects the Gricean maxims of Quantity 1 as well as Manner 1 and 2, while the R-Principle collects Quantity 2, Relation, and Manner 3 and 4. The maxim of Quality is considered as unreducible, as truthfulness is a precondition for satisfying the other maxims (Horn, 2004: 7).

The Q-principle aims at the maximization of content. It is a guarantee for the hearer that the content is

sufficient. The hearer infers from the speaker's failure to use a more informative or briefer form that the speaker was not in a position to do so. Scalar implicatures are a case in point. The R-principle aims at the minimization of expression, and consequently, the minimization of the speaker's effort. According to Horn, this principle holds for all indirect speech acts.

The following table, which is adapted from Horn (2004: 10), shows how the Q-principle works in the case of scalar implicatures (Table 3). The two-sided reading is the default case.

According to Horn, the conflict between the Q-principle and the R-principle may be resolved, as expressed by the following principle (Horn, 1984: 22):

The Division of Pragmatic Labor

The use of a marked (relatively complex and/or prolix) expression when a corresponding unmarked (simpler, less 'effortful') alternative expression is available tends to be interpreted as conveying a marked message (one which the unmarked alternative would not or could not have conveyed).

Levinson (1987: 73) argues that Horn mixes up two things here that properly should be distinguished, namely minimization of content on the one hand, and minimization of expression on the other. According to Levinson, splitting up the maxims of Manner in the way Horn does is mistaken, because the Manner maxims are fundamentally dependent on form, and thus related to minimization of expression.

Following Horn's original work, much research has been done on Horn scales, e.g., by Hirschberg (1991), Fretheim (1992), Matsumoto (1995), Sauerland (2004), van Rooy (2004). In this connection, three further areas of research deserve to be singled out.

First, as shown in Horn (1989: Ch. 4), there is the phenomenon of *metalinguistic negation*. For example, when uttering *It's not warm, it's hot!* the first part of the utterance gives rise to the scalar implicature 'It is not hot,' but this implicature is obviously denied in the second part of the utterance. Typically, utterances of this type have a humorous, ironical, or sarcastic flair (cf. Chapman, 1996 for an overview

and Carston, 1996 and Iwata, 1998 for an echo-theoretic interpretation).

Second, there is some discussion about the exact status of the Horn scales in the lexicon, e.g., how are elements selected for scales, how is the ordering of the elements achieved, etc. An influential approach is the one by Hirschberg (1991), who argues that there exist, in addition to lexical scales, scales that are induced pragmatically or on the basis of real-world knowledge. For example, when speaker A asks *Did you get Paul Newman's autograph?* and speaker B answers *I got Joanne Woodward's*, implicating 'not Paul Newman's,' we are dealing with a salient scale of autograph prestige <Newman, Woodward>. Consequently, Hirschberg (1991: 42) denies that there is any principled distinction between GCIs and PCIs.

Third, the economical aspect of Horn's reduction of the Gricean apparatus has recently become very attractive within *Bidirectional Optimality Theory* (cf. Blutner, 2004). This theory assumes that sentences are semantically underspecified, and therefore are in need of enrichment. A function *Gen* is assumed that determines for each common ground the set of possible enrichments. Bidirectional (i.e., taking the perspective of speaker *and* hearer) Optimality Theory then stipulates that a form-meaning pair is optimal if and only if it is taken from the set defined by *Gen*, and that there is no other pair that better fulfills the requirements of the Q- and I-principle. For an application and further discussion, see Krifka (2002) (see **Pragmatics: Optimality Theory**).

Relevance Theory: Carston's Underdeterminacy Thesis

Relevance theory is a cognitive theory of meaning whose major claims are that semantic meaning is the result of linguistic decoding processes, whereas pragmatic meaning is the result of inferential processes constrained by one single principle, the *Principle of Relevance*, originally proposed in Sperber and Wilson (1995) (see **Relevance Theory**). However, the connection to the Gricean maxim of Relevance is rather weak, as can be seen from the following definitions

Table 3 Application of the Q-Principle to scalar implicatures

Statements	Lower bound, one-sided (what is said)	Upper bound, two-sided (what is implicated qua Q)
a. Pat has three children	'... at least three ...'	'... exactly three ...'
b. You ate some of the cake	'... some if not all ...'	'... some but not all ...'
c. It's possible she'll win	'... at least possible ...'	'... possible but not certain ...'
d. He's a knave or a fool	'... and perhaps both ...'	'... but not both'
e. It's warm	'... at least warm ...'	'... but not hot'

(Carston, 2002; for other versions, see Wilson and Sperber, 2004):

First (Cognitive) Principle of Relevance

Human cognition is geared towards the maximization of relevance (that is, to the achievement of as many contextual (cognitive) effects as possible for as little processing effort as possible).

Second (Communicative) Principle of Relevance

Every act of ostensive communication (e.g., an utterance) communicates a presumption of its own optimal relevance.

Carston (2002) questions the standard division of labor between semantics and pragmatics and argues that pragmatics contributes much more to the construction of explicit meaning ('what is said') than generally assumed. Her overall aim is to establish relevance theory as a theory of cognitive pragmatics. The relevance theoretic approach is, according to Carston, "to be characterized as a sub-personal-level explanatory account of a specific performance mechanism conducted at the level of representations-and-procedures" (Carston, 2002: 11).

Carston's *underdeterminacy thesis* says that linguistic meaning generally underdetermines what is said. Pragmatic inferences are not only necessary to determine implicatures, but also to fix the proposition directly expressed by an utterance. This discrepancy between the meaning encoded in linguistic expressions and the proposition expressed by the utterance of these expressions ('what is said') is illustrated by various cases (over and above the well-known cases of ambiguities and indexical resolution): missing constituents (27), unspecified scope of elements (28), underspecify or weakness of encoded conceptual content (29), overspecify or narrowness of encoded conceptual content (30):

- (27a) [Where is the book?] On the top shelf.
(= 'The book is on the top shelf.')
- (27b) Paracetamol is better. [than what?]
- (27c) This fruit is green. [which part of the fruit?]
- (28a) She didn't butter the toast in the bathroom
with a knife. [different stress changes the
information structure]
- (28b) There's nothing on TV tonight. [nothing that is
interesting for you]
- (29) I'm tired. [predicate is too weak]
- (30) Her face is oblong. [predicate is too narrow]

In all these cases, additional inferential steps are necessary to understand what the speaker intends to say.

Since linguistically encoded meanings are necessarily incomplete, pragmatics makes an essential

contribution not only to the construction of *implicit meaning* but also to the construction of *explicit meaning*. In the spirit of Relevance Theory, Carston proposes a three-level model of semantic and pragmatic interpretation of linguistic expressions.

The first step involves semantic decoding of linguistic expressions. The output of the semantic decoding is an impoverished, nonpropositional semantic representation, which Carston calls logical form. It can be described as a "structured string of concepts with certain logical and causal properties" (Carston, 2002: 57) containing slots indicating where certain contextual values must be supplied. Hence, the output of the semantic decoding device is an incomplete template or scheme, open to a range of compatible propositions.

In the second step of interpretation, the hearer reconstructs the proposition intended by the speaker through pragmatic inference. Thus, pragmatic inference bridges the gap between what is linguistically expressed (incomplete conceptual schemata/logical form) and what is said (full propositional representations). For example, when a speaker utters the subsentential expression *on the top shelf* in a given context of utterance, the hearer is supposed to reconstruct the missing constituents to yield the intended proposition 'The marmalade is on the top shelf'. The pragmatic interpretation device is constrained by the First (Cognitive) Principle of Relevance, as proposed by Sperber and Wilson (1995).

Finally, there has to be a third step of interpretation, in which the hearer determines implicatures, i.e., 'what is meant.' Thus, Carston assumes that pragmatic inference is necessary for the second and third step of interpretation. In this cognitive approach, the bulk of utterance interpretation has to be done by pragmatic inference.

The pragmatic device of interpretation relies not only on linguistic information but also on additional information gained from context, perception, and world knowledge. Here, Carston essentially refers to Searle's theory of mind, especially his notion of *Background* (cf. Searle, 1980). Utterances are interpreted against a set of more or less manifest background assumptions and practices. Consider, for instance, the following five sentences: (a) *Jane opened the window*, (b) *Jane opened her book on page 56*, (c) *Jane opened the wall*, (d) *Jane opened her mouth*, (e) *The doctor opened her mouth*. Carston assumes that the encoded meaning of the English verb *open* does not vary in all five examples, although *open* receives quite different interpretations, depending on a set of background assumptions about different practices of opening. The Background is construed as a set of weakly manifest assumptions and practices in an

individual's cognitive environment. Since the Background always supplies additional meaning to the interpretation of an utterance, the proposition expressed by an utterance cannot be fully determined by the meaning of its parts and the mode of their combination. Consequently, the principle of semantic compositionality (see Frege, Friedrich Ludwig Gottlob) does not hold for the proposition expressed, but only for the underdetermined logical form (i.e., the first step of interpretation).

As does Levinson (2000), Carston, too, argues that Grice does not account for the fact that 'what is said' is not independent from pragmatic input. However, Carston and Levinson differ in their approaches to the question of how the pragmatic intrusion problem needs to be dealt with. As shown above, Levinson develops a pragmatic subtheory of GCIs, dealing only with the pragmatic processes involved in the elaboration of 'what is said'. By contrast, Carston favors a unitary account of all pragmatic processes, irrespective of whether they contribute to the 'what is said' or to different implicated assumptions (corresponding to Levinson's PCIs).

Carston's (2002: 377) use of the terms *explicature* and *implicature*, essentially based on Sperber and Wilson's (1995: 182) distinction between explicit and implicit assumptions/propositions, is spelled out in the following way (cf. Carston, 1988):

Explicature

An ostensibly communicated assumption that is inferentially developed from one of the incomplete conceptual representations (logical forms) encoded by the utterance.

Implicature

An ostensibly communicated assumption that is not an explicature; that is, a communicated assumption which is derived solely via processes of pragmatic inference.

The difference between explicatures and implicatures lies essentially in the way they are supplied: explicatures are developments of the logical form that they contain as a proper subpart, whereas implicatures are derived purely inferentially. In regard to these two kinds of pragmatic enrichment, the cognitive approach Carston promotes motivates the distinction between 'communicated assumptions' and the 'inferential steps' leading to them. Carston argues that explicatures are construed by means of interpretative hypotheses rather than by (generalized) implicatures.

Consider the example: *John came in and he sat down.* The preferred interpretation for the personal pronoun *he* in the second sentence is the coreferential one. Following Levinson, this interpretation results from an I-implicature. Carston argues that this implicature must be a proposition like '*He* refers to whomever *John* refers to', "a propositional form

representing a hypothesis about reference assignment" (Carston, 2002: 151). She rejects the idea of reference assignment being an implicature and rather identifies it as an interpretative hypothesis like '*John came in and he, John, sat down,*' which is derived online and only confirmed if it meets the expectation of relevance. Carston claims that this strategy is able to resolve the dilemma of Grice's circle, for the simple reason that interpretation processes can be effected simultaneously.

Finally, the cognitive approach leads Carston to reject *conventional implicatures*; these are subsumed under the procedural elements. Relevance Theory distinguishes between concepts as constituents of mental representations, and procedures that constrain pragmatic inferences. Conventional implicatures conveyed by expressions such as *moreover* and *therefore* do not contribute to the conceptual part of the utterance, but point the hearer to the kind of pragmatic processes she is supposed to perform (cf. Blakemore, 2002).

Bach (1994), who tries to defend the Gricean notion of 'what is said,' criticizes the notion of explicature and proposes instead the term *implicature* (cf. also Bach, 2001). Implicatures are either *expansions* of 'what is said,' as in *You are not going to die [from this little wound]* or *completions*, as in *Steel isn't strong enough [for what?]*. In these cases, "the resulting proposition is not identical to the proposition expressed explicitly, since part of it does not correspond too any elements of the uttered sentence"; hence Bach considers it "inaccurate to call the resulting proposition the explicit content of an utterance or an explicature" (Bach, 1994: 273).

Carston views Relevance Theory as a cognitive theory of utterance understanding that aims at the subpersonal level, where processes are fast and automatic. Thus, it should be clear that this theoretical goal differs from that pursued by Grice (cf. Saul, 2002). It must be noted, however, that arguments from psycholinguistic research are called for in order to constrain the theory.

First, it may be asked how children acquire implicatures and what roles maxims, principles, and the like play in this process. There are studies on the acquisition of irony and metaphor by Winner (1988) as well as studies on the role of Gricean principles in lexical acquisition (cf. Clark E V, 1993, 2004). More recently, studies have been done on the acquisition of scalar implicatures, in particular dealing with the hypothesis that small children are "more logical" than older children and adults, in that they more readily accept the "some, perhaps all" – reading of the quantifier *some* (cf. Noveck, 2001; Papafragou and Musolino, 2003).

Second, there is some evidence that hearers do not first compute the literal meaning, then the nonliteral or indirect meaning, but that they arrive at the nonliteral/indirect meaning earlier or in a parallel fashion (cf. Shapiro and Murphy, 1993; Récanati, 1995; Gibbs, 2002; Giora, 2003). It is obvious that experimental research is very important for implicature and explicature theory (cf. Wilson and Sperber, 2004: 623–628).

Quality Reconsidered

In the development of neo-Gricean approaches to implicature such as Horn's and Levinson's, the Gricean maxim of Quality has been neglected (see **Neo-Gricean Pragmatics**). Thus, genuine pragmatic matters such as metaphor, irony, sarcasm, lying, etc. have become largely unattractive for some implicature theorists, although metaphor had been featured as a cardinal case of maxim exploitation already early on (cf. Levinson, 1983: 147–162). Relevance Theory, on the other hand, which takes a stand on Grice as well as on neo-Gricean approaches, has developed an independent theory of irony; moreover, Carston (2002: Ch. 5), analyzes metaphors as instances of *ad hoc*-concept construction. In neither of these approaches, however, does the maxim of Quality play any role (see **Metaphor: Psychological Aspects**).

First, consider *irony*. If a speaker A utters *X is a fine friend*, referring to a person who has betrayed a secret of A's to a business rival, then the first maxim of Quality is flouted (Grice, 1989: 34). Because it is obvious that A does not believe what he says, the hearer reconstructs a related proposition, i.e., the opposite of *p*. The ironical implicature qualifies for the status of an implicature, because it is calculable, context-dependent, and cancellable. Note that this substitutional analysis is in contrast to the additive nature of other types of implicature. However, this approach has been criticized for several reasons: (i) The analysis cannot account for ironical questions, requests and understatements, (ii) it cannot explain the distinction between irony and metaphor, because the latter is also explained with regard to the first maxim of Quality, and (iii), it is not fine-grained enough, because it does not follow from 'He is not a fine friend' that he is not a friend at all.

The Gricean approach to irony has been most prominently attacked by relevance theorists (Sperber and Wilson, 1981; Wilson and Sperber, 1992; Sperber and Wilson, 1998). Following Sperber and Wilson, ironical utterances have four main properties: (i) They are mentioned, not used, (ii) they are **echoic** in nature, (iii) the ironical interpretation is an implicature that

is derived through recognition of the echoic character of the utterance (Sperber and Wilson, 1981: 309), (iv) the ironical speaker displays a dissociative attitude towards the proposition uttered. Take the utterance *What lovely weather!* as an example. When uttered during a downpour, the speaker cannot mean the opposite, because this would be uninformative. Instead, he wants to convey that it was absurd to assume that the weather would be nice. Thus, the ironical utterance is a case of echoic mention of a previously entertained proposition. Types of echo include sarcastic repetition (31), attributed thoughts (32), norms (33) and standard expectations (34) (cf. Sperber and Wilson, 1998):

- (31) A: I'll be ready at five at the latest.
B: Sure, you'll be ready at five.
- (32) A: I'll be ready at five at the latest.
B: You mean at five tomorrow?
- (33) A: I'll be ready at five at the latest.
B: You are so punctual.
- (34) A: I'll be ready at five at the latest.
B: It's a great virtue to be on time!

Thus, the echo theory of irony does not imply that there is always an original utterance that is exactly reproduced. The echo theory is constrained in that most utterances cannot be interpreted as echoes, and echoic interpretations must contribute to the relevance of an utterance.

Several objections to this theory may be made (cf. Sperber and Wilson, 1998): (i) The notion of an echo is far too vague; it does not make sense to look for an echo in cases of conventional irony, e.g., when somebody utters *Boy, is it hot!* when it is icy cold. (ii) Because not every echoic mention is ironical, echoic mention is not sufficient to explain ironical interpretation. (iii) It is not clear why the substitution of the opposite should not be a starting point in the search for the dissociative attitude of the speaker towards the proposition. (iv) Relevance Theory cannot explain why hearers often fail to grasp the relevance of an ironical utterance.

Second, consider *metaphor*. For Carston (2002), metaphors are cases of *ad hoc* concept construction. *Ad hoc* concepts are those concepts "that are constructed pragmatically by a hearer in the process of utterance comprehension" (Carston, 2002: 322). Typical instances of *ad hoc* concepts come about via narrowing or broadening. *Narrowing* may be illustrated by utterances like *Ann is happy*, where the concept associated with *happy* in a particular context is much narrower than the encoded concept. The case of *broadening* is exemplified by utterances like *There is a rectangle of lawn at the back*, where it

is very unlikely that the encoded concept of *rectangle* is communicated. Both processes are cases of constructing an *ad hoc* concept that contributes to the explicature.

If metaphors are *ad hoc* concepts, then they are part of the explicature as well. Thus, in *Mary is a bulldozer*, the logical form of *bulldozer* is associated with an *ad hoc* concept BULLDOZER* differing from the concept BULLDOZER usually encoded by this word. In this approach, metaphor isn't an implicature any more, as Grice (1989) and Levinson (1983) would have it, but an explicature.

Recall that for Horn (1984), the maxim of Quality was unreducible. Since then, its domain of application has considerably shrunk. However, it still seems to play a role when it comes to the analysis of lying, deception, insincerity, and – maybe – irony (cf. Wilson and Sperber, 2002; Meibauer, 2005). In Levinson's (2000) approach, matters of irony, etc., are dealt with in the component called Gricean Pragmatics 2. Maybe it is there that the maxim of Quality will have a comeback. It is clear that some version of the maxim plays also a role in the definition of success conditions for assertive illocutions (see *Irony*).

Implicature and the Grammar/Pragmatics Interface

As has become clear from the sketch presented here of Levinson's and Carston's frameworks, pragmatic inferencing is powerful enough to influence semantic representations (see **Semantics-Pragmatics Boundary**). However, when it comes to pinpoint the exact relations of implicatures to illocutions on the one hand, and sentence types on the other, there still are many open questions.

First, consider implicatures *vis-à-vis* illocutions. Even if both are associated with an individual speech act, these notions refer to different entities: an additional proposition, in the case of implicature, vs. a type of act such as a promise, assertion, request etc., in the case of illocution.

An important connection between illocutions and implicatures is usually seen as obtaining in the case of *indirect speech acts* (see **Speech Acts; Pragmatic Acts**). According to Searle (1975), a reconstructive process that leads the hearer from the secondary illocutionary point (the 'literal' illocution) to the primary illocutionary point (the intended illocution) is similar to the scheme of reasoning that Grice proposed for conversational implicatures; step 2 of his sample derivation even includes principles of conversational cooperation (compare also the speech act schema proposed by Bach and Harnish, 1979). Accordingly, indirect speech acts have sometimes been analyzed as

implicatures, for example the question *Can you close the window?*, meant as a request to close the window, a case that is related to the R-Principle as proposed by Horn (1989, 2004).

A case in point is the *rhetorical question*. Whereas Meibauer (1986) analyzes them as indirect speech acts, i.e., interrogative sentences types associated with assertive force and polar propositional content, Romero and Han (2004) analyze negative *yes/no* questions like *Doesn't John drink?* as connected with a positive epistemic implicature such as 'The speaker believes or at least expects that John drinks.' It is not clear at first sight whether such analyses are compatible; in any case, as Dascal (1994) has shown, the notions of implicature and speech act are independently motivated, and should not be confused. Thus, the question of their interrelation requires further research.

Second, consider implicatures vis-à-vis sentence types. It is widely accepted that there is a systematic connection between sentence types such as declarative, interrogative, and imperative, etc., and illocutions such as assertion, question, and request, etc.; moreover, in some approaches the existence of an intermediate category 'sentence mood' is assumed (cf. Sadock and Zwicky, 1985; Harnish, 1994; Reis, 1999; Sadock, 2004; Zanuttini and Portner, 2003). However, while it is conceivable that sentence types determine a certain illocutionary potential, the analogical notion of an 'implicature potential' has never been proposed, probably because of the authors' concentration on lexical elements that give rise to GCIs.

However, there are several observations showing that such a concept is not totally mistaken. Consider the following examples:

- (35) Who is the professor of linguistics at Tübingen? +> Someone is the professor of linguistics at Tübingen.
- (36) [I gave the encyclopedia to Bettina.] You gave the encyclopedia to WHOM?
- (37) Visit Markus and you'll get new ideas! +> If you visit Markus then you'll get new ideas.
- (38a) This is good. +> This is not excellent.
- (38b) Is this good? *+> Is this not excellent?

In (35), we have the case of an existential implicature that is typically bound to *wh*-interrogatives, but shows the properties of variability and cancellability. (Its classification as an existential presupposition, cf. Levinson, 1983: 184, has been abandoned, because it does not survive the negation test.) Example (36) illustrates the echo-*wh*-question. As Reis (1991) has persuasively argued on the basis of German data, these sentence types are neither 'echo-*wh*-interrogatives' nor *wh*-interrogatives. Instead, these utterances

are regular instances of any sentence type, and their interrogative force is explained as a conversational implicature triggered by the *wh*-element (see also Reis, 1999). Another example showing that implicatures are sensitive to sentence types is the conditional imperative in (37) (cf. Davies, 1986; Clark, 1993). Finally, if elements that trigger scalar implicatures are in the scope of a question operator, the respective implicature may be blocked, as shown in (38) (the asterisk * denotes a blocked or unallowed implicature). In summary, then, there is evidence of a systematic interaction between implicatures and sentence types. The question is, then, how and where to account for this interaction.

A detailed analysis of the sentence type-implicature relation is developed in Portner and Zanuttini (2000). They concentrate on negated *wh*-interrogatives and exclamatives in Paduan, a northern Italian dialect spoken in the city of Padua:

(39a) Parcośsa *no* ve-to anca ti!? (*wh*-interrogative)
 Why NEG go-s.cl also you
 'Why aren't you going as well!?'

(39b) Cossa *no* ghe dise-lo! (*wh*-exclamative)
 what NEG him say-s.cl
 'What things he's telling him!'

The point is that the NEG-element has no negative force. In principle, there are two strategies for analyzing examples like (39): First, as a special type of negation, nonpropositional, expletive, or modal in character. The second strategy, as proposed in Meibauer (1990) on the basis of German data, is to assume regular negation, and to derive the modal effect from pragmatic principles. Portner and Zanuttini (2000), drawing on the latter approach, assume that exclamatives are factive. The negation particle *no* triggers a conventional implicature, which says that the lowest element from a set of alternative elements (that are possible in a contextually given scale) is true. In cases like (39a), there is an expectedness scale {less expected < more expected}, in cases like (39b), there is an unexpectedness scale {more expected < less expected}. The scales are dependent on the respective sentence type. While it is not clear (i) whether exclamatives constitute a separate sentence type at all (cf. d'Avis, 2001), (ii) why the implicatures are of the conventional type, and (iii) how the relevant scales are obtained from the context, it should be clear that such an approach paves the way for a more empirical research on the interplay of sentence types and implicatures.

Conclusions

On the basis of the foregoing sketch of three major approaches to implicature theory, we may state some of the prevailing tendencies. To begin with, there is

a striving to understand implicatures in terms of economy. This is true for Levinson's insight that implicatures help to overcome "the slowness of articulation," as becomes clear from his slogan "inference is cheap, articulation expensive" (Levinson, 2000: 29), as well as for Horn's appeal to the principle of least effort and Sperber and Wilson's view on optimal relevance. Lately, recent developments in Optimality Theory have shown attempts to integrate the interplay of maxims into their frameworks.

Second, there is a tendency to reject the classic dual distinction between 'what is said' on the one hand, and 'what is implicated' on the other. Instead, a three-level approach to meaning is favored, cf. the distinction in Levinson (2000: 21–27) between sentence meaning, utterance type meaning, and speaker meaning, or Carston's three-level model of utterance interpretation. However, there is considerable terminological confusion here, as the diagram in Levinson (2000: 195) impressively shows; confusion that has to do with the still unsolved problem of finding demarcation lines or fixing the interfaces between 'what is said' and 'what is meant.' Further discussion of the question of level architecture can be found in Récanati (2004).

Obviously, the second tendency is connected with the widely accepted view that some sort of underdeterminacy thesis is correct, and that there are presemantic pragmatic processes that are input for model-theoretic interpretation (cf. Levinson, 2000: 188), or are necessary to fix full propositional representations (cf. Carston, 2002).

As has become clear, there are still many problems to solve: the status of the maxims of Relevance and Manner, the distinction between GCI and PCI, the status of conventional implicatures, the interaction of implicatures with illocutions and sentence types, to name only a few. Besides, the role that implicatures play in many areas, such as those of language acquisition and language change, awaits much further research.

Indexicality: Theory

A Ponzio, University of Bari, Bari, Italy

Indexicality in Peirce's Categories and Sign Typology

'Indexicality' is a feature of the 'index,' one of three types of signs identified by Charles S. Peirce, the other two being the 'icon' and 'symbol.'

According to Peirce, a sign is something that stands for something else, in some respect. It creates in the mind of the interpreter an equivalent sign, or perhaps a more developed sign, that is, an interpretant (2.228 – As is common in Peircean scholarship, quotes and citations will be identified by volume and paragraph number from Peirce [1931–1958]).

That the sign stands for something in some respect means that it does not refer to the object in its entirety (dynamic object), but only to a part of it (immediate object). Furthermore, a sign subsists for Peirce according to the category of 'thirdness,' that is, it presupposes a triadic relation between itself, the object, and the interpretant thought, which is itself a sign. And given that it mediates between the interpretant sign and the object, the sign always plays the role of third party.

The icon is characterized by a relation of similarity between the sign and its object.

The symbol is a sign "in consequence of a habit (which term I use as including a natural disposition)" (4.531). The symbol is never pure but contains varying degrees of indexicality and iconicity; similarly,

as much as a sign may be characterized as an index or icon, it will always maintain the features of symbolicity: a sign to subsist as such always requires the mediation of an interpretant and recourse to a convention.

The index is a sign that signifies its object by a relation of contiguity, causality, or by some other physical and mechanical connection. This relation also depends on a *habitus* or convention: e.g., the relation between hearing a knock at the door and someone on the other side who wants to enter. Convention relates the knocking to the knocker, but contiguity/causality predominates to the point that we are surprised if we open the door and nobody enters. Types of index include: (1) 'symptoms,' medical, psychological, natural, or social phenomena (actual contiguity + actual causality); (2) 'clues,' natural phenomena, attitudes, and inclinations (presumed contiguity + nonactual causality); (3) 'traces,' physical or mental (nonactual contiguity + presumed causality). "An 'index,'" says Peirce, "is a sign which would, at once, lose the character which makes it a sign if its object were removed, but would not lose that character if there were no interpretant" (2.304).

Signs subsist in the dialectic between symbolicity, indexicality, and iconicity. The symbol is never pure but contains varying degrees of indexicality and iconicity; similarly, a sign that is prevalently indexical or iconic maintains the characteristics of symbolicity – it requires the mediation of an interpretant sign and recourse to a convention.

Symbolicity refers to the sign's conventional character, the relation of constriction by convention between a sign and its object established on the basis of a code, a law. To say it with Peirce: "I define a Symbol as a sign which is determined by its dynamic object only in the sense that it will be so interpreted. It thus depends either upon a convention, a habit, or a natural disposition of its interpretant, or of the field of its interpretant (that of which the interpretant is a determination)" (letter from Peirce to Welby, 12 October 1904, in Hardwick, 1977: 33).

Indexicality refers to the compulsory character of the sign, to the relation of cause and effect, of necessary contiguity between sign and object: "I define an Index as a sign determined by its dynamic object by virtue of being in a real relation to it" (Hardwick, 1977: 33). The index requires mediation by an interpretant sign and recourse to a convention. But in the case of the index, unlike symbols, the interpretant does not decide on the object. On the contrary, the relation between sign and object preexists with respect to interpretation, it is an objective relation and in fact conditions interpretation. The sign and that which it stands for are given together independently of the

interpretant. Nonetheless, this independence does not exclude the necessity of recourse to a convention to organize the relation between sign and object as a sign relation.

Indexicality belongs to the category of 'secondness,' one of Peirce's three categories, the other two being 'firstness' and 'thirdness.'

- Firstness is the mode of being of that which is such as it is, positively and without reference to anything else.
- Secondness is the mode of being of that which is such as it is, with respect to a second but regardless of any third.
- Thirdness is the mode of being of that which is such as it is, in bringing a second and third into relation to each other (8.329).

Firstness (in-itselfness, originality), secondness (over-againstness, obsistence) and thirdness (in-betweenness, transuasion) are universal categories. Peirce's categories help to explain logicocognitive processes and therefore at once the formation of signs. Analyzed in terms of Peirce's typology of signs, firstness coincides with the sphere of iconicity. Something that presents itself as firstness, presence, 'suchness,' pure quality is characterized by the relation of similarity (1.356–1.358). Analyzed in terms of Peirce's typology of signs, thirdness coincides with the sphere of symbolicity. Together with the other two categories, thirdness guides and stimulates inquiry and therefore has a heuristic value. The inferential relation between premises and conclusion is based forever on mediation, that is, on thirdness.

Secondness is the category according to which something is considered relatively to or over against something else. It involves binarity, a relation of opposition or reaction. From the viewpoint of signs, secondness is connected with indexicality. The icon, which is governed by firstness, presents itself as an original sign, the symbol, which is governed by thirdness, as a transuational sign, while the index, which is governed by secondness, is an obsistent sign (2.89–2.92).

Any sign may be taken as something in itself, or in relation to something else (its object), or as a go-between (mediating between object and interpretant). On the basis of this threefold consideration, Peirce establishes the following correspondences between his trichotomy of the categories (all his trichotomies contain thirdness insofar as they are trichotomies) and three other important trichotomies in his semiotic system: firstness: qualisign, icon, rheme; secondness: sinsign, index, dicisign (or dicent sign); thirdness: legisign, symbol, argument (2.243). Symbolicity is the sign dimension that shares most in thirdness, because it is characterized by mediation (or in-betweenness),

iconicity by firstness or immediacy (or in-itselfness), and indexicality by secondness (or over-againstness). The category of secondness, together with firstness and thirdness are the omnipresent categories of mind, sign, and reality (2.84–2.94).

On the level of the typology of signs, firstness, secondness, and thirdness correspond to iconicity, indexicality, and symbolicity; on the level of logic, they correspond to abduction, deduction, and induction; and on the level of ontology, to agapism, anancism, and tychism.

From the viewpoint of logic, inference regulated by secondness and indexicality corresponds to deduction (while inference regulated by firstness and iconicity corresponds to abduction, and inference regulated by thirdness and symbolicity corresponds to induction). In fact, in the case of an ‘obsistent argument’ or deduction, the conclusion is compelled to acknowledge that the facts stated in the premises, whether in one or both, could not be if the fact stated in the conclusion were not there (2.96).

Indexicality and Logic

From the viewpoint of ontology, of universal being, secondness, and in sign typology, indexicality is present in the law of ‘anancism’ or necessity. According to Peirce, this necessity regulates the evolutionary development of the universe together with ‘agapism’ (creative love, which corresponds to firstness) and ‘tychism’ (causality, which corresponds to thirdness) (6.287–6.317).

To indexicality and respectively secondness or obsistence, a binary category, there corresponds a relation of relative alterity in which the terms of the relation depend on each other. Effective alterity, the possibility of something being-on-its-own-account, absolutely, *per se*, autonomously, presents itself as firstness, or orience, or originality, according to which something “is what it is without reference to anything else within it or without it, regardless of all force and of all reason” (2.85). An effective relation of alterity is not possible in terms of binarity, indexicality, secondness, obsistence. Relations of alterity are not possible in a system regulated exclusively by secondness, therefore, binarity, where an element exists only on the condition that it refer to another element and would not exist should this other element be negated. “Take, for example, a husband and wife. Here there is nothing but a real twoness; but it constitutes a reaction, in the sense that the husband makes the wife a wife in fact (not merely in some comparing thought); while the wife makes the husband a husband” (2.84).

In the succession deduction–induction–abduction, the degree of alterity increases. Says Peirce:

“Abduction is the process of forming an explanatory hypothesis. It is the only logical operation which introduces any new idea; for induction does nothing but determine a value, and deduction merely evolves the necessary consequences of a pure hypothesis. Deduction proves that something **must** be; induction shows that something **actually** is operative; abduction merely suggests that something **may be**” (5.172). Abduction is the inferential process by which the rule that explains the fact is hypothesized through a relation of similarity (iconic relation) to that fact. This rule that acts as the general premise may be taken from a field of discourse that is close to or distant from that to which the fact belongs, or it may be invented *ex novo*. If the conclusion is confirmed, it retroacts on the rule and convalidates it (ab- or retro-duction). Such a retroactive procedure makes abductive inference risky, exposing it to the possibility of error; at the same time, if the hypothesis is correct, the abduction is innovative, inventive, and sometimes even surprising.

Peirce connected indexicality and deduction:

An Obsistent Argument, or **Deduction**, is an argument representing facts in the Premiss, such that when we come to represent them in a Diagram we find ourselves compelled to represent the fact stated in the Conclusion; so that the conclusion is drawn to recognize that, quite independently of whether it be recognized or not, the facts stated in the premisses are such as could not be if the fact stated in the conclusion were not there; that is to say, the Conclusion is drawn in acknowledgment that the facts stated in the Premiss constitute an Index of the fact which it is thus compelled to acknowledge (2.96).

Indexicality and Dialogicality

In inference, the relation between the premises and conclusion may be considered in terms of dialogue between ‘interpreted signs’ and ‘interpretant signs’ (Ponzio, 1990: 49–61). The degree of dialogicality and alterity is low in induction – where the relation between premises and conclusion is determined by habit and is of the symbolic type – and in deduction – where the conclusion is a necessary derivation from the premises in a relation of the indexical type. To be precise, the degree of dialogicality in the relation between interpreted (premises) and interpretant (conclusion) (an indexical relation) is minimal in deduction: once the premises are accepted the conclusion is compulsory. Induction (where the relation between premises and conclusion is symbolic) is also characterized by unilinear inferential processes: identity and repetition dominate, but the relation between premises and conclusion is no longer compulsory. Instead, in abduction the relation between the

argumentative parts is dialogic in a substantial sense. The relation between premises and conclusion is predominantly iconic, therefore a relation of reciprocal autonomy. Consequently, abductive inference can generate sign processes at high levels of dialogicality and otherness, therefore responses that are risky, inventive, and creative with a minimal margin for convention or symbolicity and mechanical necessity or indexicality.

An approach to indexicality in terms of dialogue has its source in a theoretical framework that may be identified as Peircean-Bakhtinian (from the Russian philosopher Mikhail Bakhtin; see **Bakhtin, Mikhail Mikhailovich**), and its basis in the distinction between ‘formal dialogicality’ (which refers to the fact that a text is enacted or represented in the ‘form of a dialogue’) and ‘substantial dialogicality’ (which concerns the ‘degree of dialogicality’ in a given text, whether formally a dialogue or not). These two concepts of dialogicality do not necessarily coincide: a formal dialogue does not necessarily imply substantial dialogue, while the latter does not necessarily take the form of a dialogue. Signs and arguments are formally dialogical as the result of a dialogue between interpreteds and interpretants, according to varying degrees of dialogicality. From a semiotic perspective, the relationship between interpreteds and interpretants results in signs which – on a scale ranging from a maximum degree of monologism to a maximum degree of dialogism, otherness, and creativity – may be (prevalently) indexical, or symbolic, or iconic; from the perspective of logic, the relationship between interpreteds (premise) and interpretants (conclusion) results in arguments or inferences and is of the deductive, inductive or abductive type. The varying balance in indexicality, symbolicity, and iconicity in any given sign situation, whether formally a dialogue or not, involves variations in the degree of otherness and dialogicality regulating the relationship between the interpreted (premise) and interpretant (conclusion) of an argument: therefore, argumentative value may also be measured in terms of the degree of substantial dialogicality (Ponzio, 1990: 215–232).

Theory of Indexicality in a Peircean Semiotic Framework

Peirce’s recognition of the need for the index may be connected with his interest in Duns Scotus’s realism and the notion of *haecceitas* (thisness), which indicates the single thing in contrast to universality, i.e., the reality of actuality or secondness: “hic and nunc,” Peirce observes, “is the phrase perpetually in the mouth of Duns Scotus” (CP 1.459). “The index has the being of present experience” (4.447) of *hic* and *nunc*. An index “is a sign which refers to the Object

it denotes by virtue of being really affected by that Object” (CP 2.248), where the word “really” resonates to Scotus’s doctrine of *realitas et realitas* (Sebeok, 2001: 87). To demonstrate the centrality of indexicality in Peircean semiotics, Thomas A. Sebeok (2001) observed that Peirce contended that no matter of fact can be stated without the use of a sign serving as an index, because ‘designators’ compose one of the main classes of indexes and because designation is “absolutely indispensable both to communication and to thought. No assertion has any meaning unless there is some designation to show whether the universe of reality or what universe of fiction is referred to” (8.368). Indexes “whose relation to their objects consists in a correspondence in fact . . . direct the attention to their objects by blind compulsion” (1.558). Deictics of various kinds, including tenses, that offer the most clear examples of indexicality.

Indexicality, iconicity, and symbolicity are three complementary rather than antagonistic categories. Peirce returned repeatedly to his sign typology. By 1906, he had classified 66 different types of signs. However, the most important in all his reflections on signs was a trichotomy formulated in relation to his original typology and presented in an article of 1867, ‘On a new list of categories’ (1.545–1.559). With this trichotomy, Peirce identified three types of signs: icons, indexes, and symbols. Sebeok evidenced that all three are present in nonhuman semiosis as well (for a synthesis of the comparison between the human world and the world of other animals relatively to this typology, see Sebeok, 2001). From the perspective of sign types, there is no difference between human and nonhuman semiosis. In the light of Sebeok’s research, it is now clear that icons, indexes, and symbols are present both in languages (which are human) and in nonlanguages.

As Sebeok observes, elaborating on Peirce’s typology, not signs but sign aspects are the object of classification. The hybrid character of the sign should now be obvious with respect to its distinction into symbol, index, and icon. The Peircean conception of the relation between symbol, icon, and index has very often been misunderstood. In fact, these terms were thought to denote three clearly distinguished and different types of sign, each with characteristics so specific as to exclude the other two. Now we know that signs that are exclusively symbols, icons, or indexes do not exist in the real world. Furthermore (and what most interests us here) in Peirce’s theory, the symbol is a mere abstraction. It is never conceived as existing as a pure symbol but is always more or less mixed with iconicity and indexicality, or to say it with Peirce, it is always more or less ‘degenerate.’

This denotation implies that more than being signs in their own right, the icon and index represent different levels in ‘degeneracy of the symbol.’ The symbol is not purely a symbol but almost always takes the characteristics of either the icon or index. The symbol may be represented iconically as a body in a state of unstable equilibrium, in which the stabilizing symbolic force is counteracted by iconic and indexical forces. But this image establishes a relation of contrast between symbol, index, and icon, when in fact they are not separate or distinct, nor are they in a relation of opposition.

Otherwise, with respect to the symbol, we would have signs that are purely icons or purely indexes and not simultaneously symbols; or symbols with no traces of iconicity or indexicality. Perhaps the image that best accounts for the relation of the symbol to the index and icon is that of a filigreed transparency with uneven traces of iconicity and indexicality, as opposed to pure transparency.

Indexicality is at the core of the symbol, given that the symbol depends on the interpretant as a result of its relation to the object. This relationship is what makes a sign a symbol. This result means that transuasion, which characterizes the symbol as a transuational sign, is considered in its obsistent aspect (2.92), and that the index is an obsistent sign. On the other hand, insofar as it is determined by the instances of what it denotes and being a general type of law, the symbol entails indexicality. In the sign considered as a symbol, identity hinges upon the alterity of the sign, which is determined by mediation of the interpretant, so that, insofar as it is a symbol, “a sign is something by knowing which we know something more” (8.332). However, this expansion is so because the sign is not only a symbol, or better, the very fact of being a symbol involves iconicity and indexicality given that thirdness, the mode of existence of the symbol, presupposes firstness and secondness or originality and obsistence, which correspond respectively to the icon and index.

From the viewpoint of its relation to the object, the sign is a symbol insofar as it involves the mediation of an interpretant; from the viewpoint of its relation to the interpretant, the sign-symbol is an Argument. This statement is true if the sign-symbol distinctly represents the interpretant that it determines as its Conclusion through a proposition that forms its Premise, or more generally, its premises (2.95). Depending on the type of sign relation established in the argument between premises and conclusion, three kinds of arguments are possible: Deduction, Induction, and Abduction. Though differentiated, all three belong to the sphere of the symbolic and are of the transuational order.

Peirce used the term ‘Transuational logic’ to indicate the doctrine of the general conditions of

determination of the interpretant (the conclusion) through propositions acting as premises (2.93). But three types of arguments are possible because they do not belong to the sphere of the symbolic alone. This means that not only the category of Transuasion comes into play but also that of Originality and Obsistence (2.84–2.96). In Peirce, the term Symbol indicates the genuine Sign obtained by abstracting from the two levels of ‘degeneracy’ of the sign. These are: the minor level – that of the Index; and the major level – that of the Icon. In the Symbol or genuine Sign, signification depends on the relation to the interpretant, whereas in the Index and Icon the capacity to signify is relatively autonomous with respect to the relation to the interpretant (2.92).

By virtue of the relation between icon, index, and symbol – a relation neither of autonomy and indifference nor of opposition, but rather of reciprocal implication – the sign is at once identical to itself and other.

The relation of implication changes in balance depending on whether the iconic, symbolic, or indexical aspect dominates, which is determined by the type of semiosis in course. All signs are symbols to the extent that they signify through mediation of an interpretant, but precisely because of such mediation they are not symbols alone.

In Peirce’s semiotics, symbols, indexes, and icons overlap in such a way that if the symbol were purely symbolic, the relation between premises and the conclusion in the argument would paradoxically be indexical and not symbolic, and would not, in fact, give rise to a transuasive argument or induction. The latter presupposes a hypothesis resulting from a preceding abduction that implies iconicity (2.96). Let us suppose that the relation between premises and conclusion is purely analytical and is wholly contained within the symbolic universe, the conventional/arbitrary, the Law; in other words, let us suppose that the relation between the symbol and interpretant is of mere identity. In this case, the relation between premises and conclusion is deductive and as a constrictive argument, it is endowed with the character of indexicality.

Mutual complicity between symbol, icon, and index should now be obvious. These three different shades of the sign are in turn implied in the cognitive process. This implication means that they are at once categories of logic and semiotics (Ponzio, 1990: 197–214).

Indexical Types of Verbal and Nonverbal Signs and Signals

The main types of indexical signs include: (1) symptoms, (2) clues, and (3) traces. Let us consider them in detail.

In the case of the symptom, the relation of the interpretant to the interpreted is of contiguity and causality: blotchy skin (interpreted), liver disease (interpretant); smoke (interpreted), fire (interpretant).

In the case of the clue, the relation of the interpretant to the interpreted is of causality (but not given in present time), on the basis of a presumed relation of contiguity: a cloudy sky as a sign that it will rain; a bloodstain on a glove as a clue that the owner is the assassin.

In the case of the trace, the relation of the interpretant to the interpreted is of contiguity (not given in present time) on the basis of a presumed relation of causality: a footprint is interpreted as the trace of a man or animal; a phobia as the trace of a certain event.

Symptoms, clues, and traces are not produced as the repetition of a pre-established interpretant of identification: they are not the result of a coding process, nor are they endowed with communicative intentionality (otherwise they would be signals: smoke used to signal one's presence or to transmit messages; footsteps left expressly by a person to signal his or her trajectory). However, these signs are interpretable because of their typicality, that is, they are already known, they have already been seen, and they repeat certain distinctive features. A preliminary moment of identification or recognition is also necessary: a footprint repeats certain distinctive features that characterize it as the imprint left by an animal, a man's or woman's shoe, a bare foot; if left by an animal, it may be characteristic of a horse (whether shod or not), a deer, etc. Similarly, a certain somatic fact appears as a symptom insofar as it repeats characteristics that identify it as that particular symptom and that link it to pathological state; in the same way, clouds mean rain if they are identified as that certain type of cloud that carries rain.

Thus traces, symptoms, and clues, too, have an identification interpretant that is determined on the basis of one's own experience or of others, and is established on the basis of a given tradition or social practice.

Similarly to signals, the relation between interpreted and interpretant is fixed on the basis of a law: in fact, handbooks are available for identification of given types of symptoms or clues or traces on the basis of specific distinctive features. A handbook of medical symptomatology or hunting are two such examples. By consulting handbooks as though they were signal codes or language dictionaries, specific traces, symptoms, or clues may be decoded even when one has no previous direct experience of them.

In some cases, symptoms, clues, or traces are produced intentionally and are predetermined by the identification interpretant in the course of their

very production. In such cases, they function as signals, even if masked as symptoms, clues, or traces. An actor who recites rage or fear, a person who pretends to be moved, feigns illness, leaves footprints on the ground so as to be followed (e.g., to set a trap), or to divert the pursuer, intentionally produces symptoms, clues, and traces according to distinctive features foreseen by the identification interpretant. Therefore, contrary to what the interpreter believes, the latter does not come into play exclusively when such features are being decoded (Ponzio, 1990: 44–36).

In signals disguised as symptoms, clues, or traces, the success of pretence depends on the fact that these signs remain distinct from signals, that is, they appear to be uncoded and devoid of an identification interpretant produced intentionally by a sender: they must not seem characterized by the identification interpretant 'at the source,' but only when they are actually being read and decoded. Thus, those cases in which symptoms, clues, and traces are signals highlight the distinction between such signs and signals as well as the distinction between the latter and verbal signs in their signal dimension rather than generally invalidating this distinction, that is, between the signs in question and signals.

Besides acting as signals, verbal signs, when such aspects as those mentioned in the preceding paragraph come into play, may also function as symptoms, clues, or traces: without speaker or writer intention, a piece of discourse, whether written or oral, may be read as indicating a specific social status or place of origin, it may betray impatience or uneasiness, foresee a certain development in the relation between interlocutors, indicate that the person speaking is in a hurry to conclude the conversation, etc. We qualify verbal signs that are symptoms, clues and traces as paraverbal signs.

Therefore, verbal signs have dual signality: as far as they are intentional, they are also signals, and as far as they are unintentional, they may also be symptoms, clues, and traces. Dual signality in verbal signs becomes triple when unintentionality is recited, calculated, or feigned, that is, when that which seems to be a symptom, clue, or trace in the verbal sign is, in reality, a disguised signal.

Indexicality in Verbal Language

Indexicality is discussed by Peirce to solve the problem of the connection between verbal language and referents in the real world. Verbal language is characterized by conventionality and 'diagrammatization.' Diagrammatization makes verbal language a 'sort of algebra'; consequently, it seems to be a sphere apart, separate from its objects. But thanks to indexicality, that is, to an association of contiguity, verbal language is not reducible to an algebraic system.

Indexicality enables language to pass from the level of diagrammatization to the level of application of its diagrams.

The relation between the phonia *book*, the object *book*, and the graphia *book* is 'conventional': however, traces of indexicality are also present, owing to the relation of contiguity established between phonia and object, and phonia and graphia. In this case, contiguity would seem to be established 'by convention.' But once this convention has been learned, it is a bond and continues to subsist thanks to the fact that the name and the object or the phonia and the graphia of the same word are given in a relation of continuity (Ponzio, 1990: 37–43).

Jakobson studies the indexical factor in verbal language in 'Shifters, verbal categories and the Russian verb' (1971 [1957]). The indexical function in verbal signs is carried out by a special class of grammatical units he calls 'shifters.' As characterized by Jakobson, shifters are 'symbol-indexes' because their dominant aspect is given in the combination of indexicality with conventionality (see Jakobson, Roman).

An example of shifters is the personal pronoun. On one hand, *I* is conventional because we can only know what it means if we know the convention on the basis of which we interpret it as referring to its object under some aspect (a person considered under the aspect of speaking subject) and therefore as situated on the same interpretive trajectory as *ego*, *je* and *moi*, *ich*, *io*, etc. From this point of view, the sign *I* is a symbol. On the other hand, in order to refer to its object, that is, to the speaker, it must be in an 'existential relationship' with it. Therefore, *I* is also an index. The personal pronouns *I* and *you* may be interpreted as referring **alternatively to the same object**, according to whether it carries out the function of 'speaking subject' or 'subject spoken to.' This multiplicity is possible on the basis of a convention and at once on the basis of the fact of functioning as an index in the literal sense of a pointing finger.

Indexicality plays a fundamental role in verbal language. As Sebeok observed (1991: 128–143), Peirce highly valued the function of shifters owing to the connection between verbal language and its referents. Designations – exemplified by the various types of deixis, including verbal tenses – said Peirce:

... are absolutely indispensable both to communication and to thought. No assertion has any meaning unless there is some designation to show whether the universe of reality or what universe of fiction is referred to. (8.368, note 23)

Two texts by Peirce on 'indexicality' in verbal language seem particularly significant, a paper of 1892 and another of 1893 (respectively in the third and

fourth volumes of *Collected papers*). Peirce considers the problem of indexicality as part of his quest to solve the problem of how verbal language, characterized by diagrammatization, which makes it like algebra, is able to connect up with its referents. This connection is only possible, says Peirce, thanks to indexicality, that is to say, association of contiguity:

It is not the language alone, with its mere associations of similarity, but the language taken in connection with the auditor's own experiential associations of contiguity which determines for him what house is meant. It is requisite then, in order to show what we are talking or writing about, to put the hearer's or reader's mind into real, active connection with the concatenation of experience or of fiction with which we are dealing, and, further to draw his attention to, and identify, a certain number of particular points in such concatenation. (3.419)

The function of indexicality is to make language pass from the level of diagrammatization to the level of application of its diagrams. The recurrent distinction between subjects and predicates of propositions, implies the distinction, says Peirce, between the indicative part of discourse and what it affirms, questions, or commands about it.

Indicatives assert nothing (2.291). They only serve to draw attention to something, and if compared to verbs, they would be considered as imperatives, such as *be careful*, *look there*. Words like *this* or *that* "have a direct, forceful action upon the nervous system, and compel the hearer to look about him," says Peirce, "and so they, more than ordinary words, contribute towards indicating what the speech is about." Concerning the term 'pronouns' used for such words as *this* or *that*, Peirce observes that nouns would be more appropriately designated as "pro-demonstratives" (3.419), as substitutes of indicators, that is deictics.

Terms like *this* or *that* are indexes with the function of drawing attention to what one means no differently from the expression *attention!* or similar cries. Terms like *this* or *that* refer to other words in written discourse; in this case, their function is no different from the relative pronouns *who* or *which*, etc., nor from use of the letters of the alphabet to indicate the issue in question in a text (naturally on the understanding that similar letters stand for the same thing). These terms continue to function as indexes that "de-algebrize" language (2.287).

"A possessive pronoun," said Peirce, "is an index in two senses": in the sense that it indicates the possessor, and in the sense that it denotes the thing possessed.

Peirce attributed the character of indexicality to indefinite pronouns such as *any*, *every*, *all*, *none*, *whoever*, etc., which he called 'universal selectives';

and to indefinite pronouns like *some*, *something*, *somebody*, which he called ‘particular selectives.’

Furthermore, adverbs of place and time, etc., must also be taken into consideration in relation to indexicality, together with such expressions as *the first*, *the last*, *the seventh*, *the first part*, etc., and prepositions and prepositional phrases such as *above*, *below*, *to the right of*, *to the left of*, etc. (2.289–2.290).

Peirce also observes that while terms that carry out an iconic function in discourse – similarity, quality, etc. – may be described, those, instead, with the function of index escape description.

Given that it is the ultimate condition of semiosis and communication, indexicality may be considered as the extreme limit of semiotic description.

Institutional Talk

I Magalhães, Universidade de Brasília,
Brasília, Brazil

© 2006 Elsevier Ltd. All rights reserved.

Institutional talk has been analyzed extensively by conversational analysts. Drew and Heritage (1992: 3–4) define it in the following way: “the institutionality of an interaction is not determined by its setting. Rather, interaction is institutional insofar as participants’ institutional or professional identities are somehow made relevant to the work activities in which they are engaged.” By disembedding talk from its institutional setting, this view misses the real point about institutional language: the fact that it is situated (Gumperz, 1982) (*see Context, Communicative*).

Institutional talk is embedded in power relations, and in order to understand what is really at stake, these relations have to be made explicit. Fairclough (1989) draws attention to the different meanings of the term ‘power.’ We can think of physical power, as of one person over another. However, institutional power is usually enacted by consent. Power can be seen as both a product and a process by which the members of an institution organize their activities. For Foucault (1980: 98), power is exercised through a “net-like organisation,” in which individuals are participants both as its “consenting target” and as the “elements of its articulation.” This means that

the subaltern positions in an institution (for example, patients in hospitals) contribute in certain ways to unequal power relations, by accepting as the natural order of things that doctors in “standard medical interviews” should have interactional control over the distribution of turns at talking, the selection and change of topics, and what kind of questions are answered (Fairclough, 1992: 138–139) (*see Power and Pragmatics; Discourse, Foucauldian Approach*).

As Mey notes, “the case of the medical interview is an outstanding instance of the institutionalized discourses in which the value of the individual’s linguistic expression is measured strictly by the place he or she has in the institution. Only utterances which meet the criteria of the official discourse are allowed...” (Mey, 2001: 301).

Institutional talk is often gendered (Graddol and Swann, 1989). In the following example in my study of doctor–patient communication in Brazil, a doctor manipulates a woman into breastfeeding her baby, against her argument that she has to go to work (Table 1) (Magalhães, 2000: 159–163).

The doctor’s male authority is manifested in an absolute interactional control, in terms of the topic and the turns at talking. In terms of the topic, he controls entirely what is talked about, commanding the mother, with verbal and nonverbal arguments (for example, by hitting his desk), to go back to breastfeeding.

Table 1 Example of institutional talk in doctor–communication

Summary of the woman's arguments	Summary of the doctor's arguments
She has to go to work. Work demands involvement, making it difficult to go on breastfeeding. She is weak, and her milk does not feed the baby properly. So the baby is hungry	Breastfeeding must be applied in all cases. The doctor does not discuss the woman's particular case. In fact, he does not even explain why the baby has to be breastfed. He counters her argument that her milk does not feed the baby properly by saying that it does

The doctor furthermore controls turn-taking by overlapping speech, as when the woman notes that when she breastfeeds, the baby is still hungry. Overall in this example, we see how institutional talk is embedded in power relations by means of the interactional control exercised by those in power (*see also Gender and Language*).

Interactional Sociolinguistics

J J Gumperz, University of California, Berkeley, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

'Interactional sociolinguistics' (IS) can be described as the application of interpretive methods of discourse analysis to gain detailed insights into the many communicative issues that arise in today's social environments, by means of systematic investigation of how speakers and listeners involved in such issues talk about them in the conduct of their affairs. This description is couched in general terms and includes a minimum of technical terminology, but it builds on premises that need to be spelled out in more detail. For instance, the notion of 'discourse' has become widely used in the general academic literature, with such expressions as the 'discourse(s)' of science, of mathematics, or of psychiatry. These terms often replace established categorizations for disciplines or specialist activities as a way of focusing on what practitioners do rather than relying on established nominal labels.

'Formal linguists' are concerned with the grammatical rules of specific languages and dialects and look at discourse as a string of utterances that can be reduced to the grammar and lexicon of constituent sentences and analyzed by established analytical

procedures. 'Sociolinguists,' on the other hand, deal with the talk of individuals speaking as members of specific groups and engaging in context-bound encounters where, along with grammar and lexicon, social and cultural forces constrain both what can be said and how it can be said. It follows that to participate in an encounter requires both linguistic and social knowledge.

But how does language interact with the social? Earlier sociolinguistic investigations turned to the published ethnographic literature for social information. In today's complex and rapidly changing societies, however, established social science concepts such as class, gender, and ethnic group cannot account for the ever-increasing diversity of the social ecologies in which we live. Social knowledge is increasingly seen as constructed through interaction. Discursive practice, the argument goes, rests on interaction, requiring the active participation of speakers and listeners, who use knowledge of the entire semiotic situation – of which speaking is a part – along with their linguistic knowledge to understand what is intended at any one point.

Theoretical Roots

A main motivation for interactional linguistic research is the search for replicable qualitative methods

of sociolinguistic analysis that can provide insights into the inherent linguistic and cultural diversity that characterizes current communicative environments. These methods are also used to document the impact of the diverse environments on members' everyday lives without relying on traditional social science categorizations. It is by now evident that diversity can no longer be treated as primarily a matter of distinctions among bounded, locally homogeneous language/culture units. Regardless of where we live, diversity is all around us. A large and ever-growing number of empirical sociolinguistic studies testify to its extent and significance, even in areas and domains of activity traditionally considered to be monolingual and monocultural. Questions of diversity loom large in public debates and in the recent social science writings that have greatly transformed our current thinking about social and cultural phenomena. Yet so far most attempts to deal with the communicative import of diversity, particularly its role in everyday communication, continue to rely on essentialized, taken-for-granted notions of culture and group on the one hand and dialect, style, or speech variety on the other. Such attempts to explain what happens in talk in terms of extra-communicative notions, whose relationship to real-life discursive practices is highly questionable, are unlikely to yield replicable results.

The 1960s writings on 'ethnography of communication' (EC) in a sense laid the foundation for current IS research. In his well-known 1960s critique of post-World War II Whorfian studies, Hymes (1962) argued that the failure of current research to provide empirical validation of relations between linguistic and cultural variability may be a result of the fact that, contrary to the prevailing assumptions, variability is not just a matter of distinctions among community-wide, presumably homogeneous grammatical and semantic structures. As Hymes (1974) suggests, many aspects of language function, which at the time had received little attention, play a major and often crucial role. His early programmatic writings set out an initial program for comparative research on both structure and function. The main argument was that such analyses, if they are to be empirically viable, must focus on specific situations of speaking, defined as interactively constituted, culturally framed encounters and not attempt to explain talk as directly reflecting the norms, beliefs, and values of communities seen as a disembodied, hypothetically uniform whole (Gumperz and Hymes, 1964, 1972). Instead of relying on community-wide generalizations as the bases for comparison, Roman Jakobson's (1960) notion of the 'speech event' was adopted as an intermediate level of analysis. Events, on the one hand, constitute

units of verbal interaction, where what is said is socially and culturally constrained, so that valid ethnographic information on what are relevant norms and constraints can more readily and verifiably be obtained by event level analysis than if one were to build on generalizations about the community-wide values. At the same time, events are made up of stretches of talk that are subject to linguistic analysis in their own terms.

The initial EC studies concentrated largely on named, bounded gatherings rather than unmarked everyday talk – public performances, ceremonies, magical rites, ritual practices, political oratory, and judicial proceedings of various kinds – such as can be found in societies throughout the world. Ethnographic research served to gather information on beliefs, values, and appropriateness norms as they applied to the event. Findings tended to be generalized by formulating 'rules of speaking,' which governed participation and conduct in the event and choice among available speech styles that made up the communities' linguistic repertoires (Bauman and Sherzer, 1989; Blount and Sanches, 1977; Sanches and Blount, 1975). Event-focused comparative investigations served to call attention to the analytical importance of situated talk and to the need for new data on inter- and intrasocietal variability of linguistic structures and language usage. Yet as Brown and Levinson (1978) demonstrated, structuralist usage rules can never be made precise enough to predict what people actually do with talk. Among other things, they fail to account for the many, often unforeseeable contingencies that govern everyday behavior, as was argued in Bourdieu's (1977, 1991) well-known critique of structuralism.

When detailed descriptions of situated performances became available, the notion of 'event' as the extralinguistically defined unit of language usage also turned out to be untenable. Anthropologist-folklorists concentrating on verbal performance discovered that, more often than not, events were not clearly bounded. Rather, the participants' definition of what the relevant context is 'emerged' in the course of the performance itself (Bauman, 1988; Bauman and Briggs, 1990; Hymes, 1981). In such cases, as Hanks puts it in a well-known article on genre: "The idea of objectivist rules is replaced by schemas and strategies, leading one to view genre as a set of focal and prototypical elements, which actors use variously and which never become fixed in a unitary structure" (1987: 681, quoted in Bauman and Briggs, 1992). That is to say, invocations of context are perhaps best seen as communicative strategies for conveying indexical information, and we do not need to confine event analysis to named entities.

Any string of utterances bounded by a detectable beginning and an ending that provide evidence for the outcome can be treated as an event.

Initial insights into the cognitive functioning of context invocation come from studies of 'code switching' (Auer, 1998), a term that is commonly used to refer to alternation among different languages or language varieties within the same community. Such alternations are found throughout the world, particularly in situations of rapid social change, and are frequently described via rules that specify the situational constraints governing language usage. In the old Roman Catholic Church service, for example, Latin was considered appropriate for prayer, while for sermons, the native language was to be employed. Yet if we examine switching as it enters into the discursive practices that constitute an event, it soon becomes apparent that the situation is more complex. As with the folk performances mentioned above, it is not the situation that determines language use; rather, it is the language or style, among other signs, which, when interpreted in relation to the ongoing talk, evokes a shift in contextual presuppositions. Code switching, in other words, functions as a metapragmatic signaling strategy that is employed indexically to suggest or evoke an 'envisionment' that yields the presuppositions in terms of which constituent messages are to be understood.

While both event evocations and code-switching function metapragmatically (Silverstein, 1976, 1993), they are 'phenomenologically distinct' (to use the current linguistic anthropologists' term). Event analysis yields general information or envisionments about what is expected in the event as a whole and what the likely outcomes are. Code switching, on the other hand, is signaled via shifts at the level of individually isolable grammatical forms. Such shifts can be seen as indexical 'contextualization cues,' which, when processed simultaneously with grammatical and lexical signs and nonlexicalized background knowledge, serve to construct the contextual ground for turn by turn, situated, sentence-level interpretation and thereby suggest how constituent messages should be understood (Gumperz, 1982). In other words, contextualization cues represent speakers' ways of providing information to interlocutors and audiences about how language is being used at any one point in the ongoing stream of talk. What sets them apart from lexicalized metadiscursive signs is that they include purely suprasegmental signs, such as stress, intonation, volume, rhythm, and so forth. Since no utterance can be pronounced without suprasegmental signs, contextualization cues are ever present in the talk. They provide direct evidence for the necessary role that indexicality plays in talk.

Contextualization strategies signal by cueing indirect inferences. Since in conversation we could not possibly express all the information that interlocutors must have to plan their own contributions and attune their talk to that of their interlocutors, it is easy to see the reason for this indirectness. But finally and perhaps most importantly, indirect (not overtly lexicalized) signaling mechanisms are for the most part culturally or subculturally specific. For example, prosody, rhythm, and phonetically marked locally specific features of pronunciation are among the principal means by which we identify where people are from and 'who' they are – that is, assess their social identity. In fact, we are socialized into society via indexical communication, and through indexical signs we indicate our 'stance' *vis-à-vis* what is happening (Ochs, 1996).

If we accept that (a) interpretation is always context dependent, and (b) that contextual presuppositions shaping interpretations are themselves subject to constant change in the course of an interaction, then we cannot expect to find the kind of one-to-one mappings of form to meanings that we associate with referential communication. Contextualization cues serve to retrieve the frames that channel the interpretive process by trimming the decision-making tree – that is, limiting the range of possible understandings.

In talking about the functioning of indexical signs in interpretation, it becomes necessary to distinguish between meaning in the linguists' sense of reference and 'situated inferences.' The latter are crucial in communicative practice. In everyday talk, situated inferences always take the form of assessment of what a speaker intends to convey by means of a message, and these are often quite different from propositional content. For example, if Giovanni and Paolo had just been talking, and I asked the former, "What did you do with Paolo?" he will not answer, "I made a statement" or "I performed a speech act." A more likely answer would be, "I asked him for a favor" or "I asked him if he was free this evening." Moreover, even if Giovanni had said, "I asked him a question," I would not take this as referring to grammatical or speech act categories but as rather as telling me what he wanted from Paolo. Communicative practices are forms of actions, and conversational inferences are made by human agents acting in the real world.

By arguing that all communication is intentional and based on inferences, we are in some ways building on Garfinkel's notion of interpretative procedures to look at the inferential aspects of speaking. But Garfinkel is not specific as to what he means by inferencing or by the 'method' by which members' interpretive processes can be retrieved, apart from

saying that we need to resort to background information on how and why a particular inference came about. How do we know what kinds of background knowledge are relevant at any one time? Is it enough simply to speak of 'extra-communicative background knowledge'? We must assume that information about contextual frames and how they interact with grammar and background knowledge is communicated in the course of discourse-level communication, where discoursing is treated as an intrinsically interactive process. It becomes necessary to clarify the specifics of what happens in the interaction as such, to assess what is intended.

Conversational analysts (Atkinson and Heritage, 1986) set out to implement Garfinkel's program. Their work has shown brilliantly what can be learned through detailed sequential analyses of speaking practices. Sequencing alone cannot by itself account for situated interpretation. Sequential ordering relies on just one of the many indexical processes that affect inferencing. Assessments of communicative intent, at any one point in an exchange, take the form of hypotheses that participants in an encounter can either confirm or reject in the course of an exchange. As conversational analysts point out, focus on members' procedures is a necessary analytical prime. The problem for IS then becomes not just to determine what is intended, but to also discover how interpretive assessments relate to the signaling processes through which they are negotiated.

How can we overcome the inherent ambiguity of inferential processes? In my own empirical field studies, I have worked out a set of procedures along the following lines. Relying on data from previously collected targeted ethnographic observations, the IS analyst begins with turn by turn scanning of the recorded materials at two levels of analysis: (a) content, and (b) grammatical form, prosody, and rhythmic organization to isolate event units. The units should be marked off from others in the recorded data by at least some thematic coherence and by detectable beginnings and ends. Lectures, ceremonies of various kinds, interviews – that is to say named units of the type normally studied by ethnographers of communication – exemplify one type of event. But event sequences can also be extracted from everyday conversations and other casual encounters. For instance, narrative sequences may alternate or come interspersed with more formal discussion, argument, banter, and the like. In performing this segmentation we seek to discover natural interactive sequences to provide empirical evidence either to confirm or disconfirm analysts' interpretations – evidence against which to test assumptions about what is intended elsewhere in the sequence. These event sequences

then form the base units for further analysis of conversational inferencing.

In phase two of the analysis, events are transcribed. The goal here is to prepare 'interactional texts' by setting down on paper all those perceptual cues – verbal and nonverbal, segmental and nonsegmental, prosodic, paralinguistic, and so on – shown by past and ongoing research to be demonstrably relied upon by speakers and listeners as part of the inferential process. This enables us not only to gain insights into situated understandings, but also isolate recurrent form–context relationships and show how they contribute to interpretation. These relationships can then be studied comparatively across events to yield more general hypotheses about members' contextualization practices.

In turning to conversational inference and its role in communicative practice, let me give some concrete examples to show how I view the process of understanding. Some time ago, while I was driving home from the office, my radio was tuned to a classical music station. At the end of the program the announcer, a replacement for the regular host who was returning the next day, signed off with the following words: "I've enjoyed being with **you** these last two weeks." I had not been listening very carefully, but the extra strong stress and volume on *you*, in a syntactic position where I would have expected an unaccented pronoun, caught my attention. It sounded as if the speaker was producing the second part of a formulaic exchange of compliments. But since there was no one else who could have spoken the first part (something like: "I enjoyed **being** with you") on the program, I inferred that by the way the host contextualized his talk, he was indirectly – without putting it "on record" – implicating (Grice, 1989) the first part, something like: "I hope you have enjoyed listening to me" (Gumperz, 1996). A second, somewhat more complex example comes from my analysis of the crossexamination transcript of the victim in a rape trial.

Counsel: "You knew at the time that the defendant was interested in you, didn't you?"

Victim: "He asked me how I'd been ... just stuff like that."

In both cases, I had to search my memory of past communicative experience to construct a likely scenario or narrative plot that might suggest possible interpretations. In example one, my initial hypothesis conflicted with what I knew from listening to the radio program. My search triggered a different, more plausible scenario. In the second example, I relied on what I knew about crossexaminations as adversarial trial proceedings, where the attorney

attempts to expose weaknesses in the defendant's testimony. But while these general facts tell us something about participants' motives in their choice of verbal strategy, we need to turn to what they actually said to understand what they intended to convey. By the words he chose, and by the way he contextualized his talk, the counsel raised the possibility that the defendant and the victim had a prior relationship. The victim's move, on the other hand, positioned as it is immediately after the attorney's question, implicates a different scenario, one where the two were merely casual acquaintances. In this way she sought to deny and in a sense ward off the questioner's potential attack on her testimony by suggesting another implicature.

I use the term 'activity' or 'envisionment' to refer to the above type of constructs. My claim is that all interpretation rests on such constructs. 'Activities' are an aspect of what Goffman (1974) calls 'frames' and are subject to constant change in the course of the exchange. That is, they do not apply to events as wholes; rather, they apply to each component move. I argue that, ultimately, all interpretation at the level of discursive practice relies on these constructs.

This view of understanding has some similarity to cognitive scientists' notions of 'scene,' but IS sees activities as evoking the actions of actors engaged in strategically formulating and positioning their moves to accomplish communicative ends in real-life encounters. In so doing, they rely on their presuppositions about mutual rights and obligations, as well as on ideologies of language and individuals' personalities, to get their message across. This implies that, in addition to meaning assessment in the established sense, there are always social relationships that are continuously negotiated and renegotiated by means of the same interpretive processes by which content is assessed.

It is useful to distinguish between two levels of inference in analyses of interpretive processes: (a) global inferences of what an exchange is about and what mutual rights and obligations apply, what topics can be brought up, and what is wanted by way of a reply, as well as what can be put in words and what is to be left implied; and (b) local inferences concerning what is intended with any one move and what is required by way of a response. In this way it becomes possible to account for changes in frame as a function of the sequential positioning of moves. Both levels of interpretation involve activities as cognitive constructs. The first is related to what Goffman calls 'framing,' while the second deals with something like the conversational analyst's 'preference organization.' While contextualization cues assist in retrieving the knowledge on which activity constructs are based,

they do not work in isolation. Interpretation always relies on cooccurring symbolic, lexical, and indexical signs. Signs such as prosodic contextualization cues, pausing, and others are usually produced and interpreted without conscious reflection and are therefore particularly useful in revealing frequently overlooked aspects of the interpretive process, which tend to be highly sensitive to cultural variability.

Interactional sociolinguistics does not claim, of course, that the methods described here solve the problem of interpretive ambiguity. The aim is to find likely solutions that are plausible in that they show how component actions cohere in the light of an event as a whole, whether it is a three-part string of moves or a longer encounter. Inferential procedures are not like assessments of the truth or falsity of specific interpretations. The method resembles conversational analysts' ways of reconstructing the general procedures that conversationalists employ in formulating specific actions. However, it goes beyond conversational analysis in that the concern is with situated online interpretation. In studies of intercultural and interethnic communication, these methods have been useful in detecting systematic differences in interpretive practices affecting individuals' ability to create and maintain conversational involvement.

Ultimately, agreement on specific interpretations presupposes the ability to negotiate repairs and renegotiate misunderstandings, agree on how parts of an argument cohere, and follow thematic shifts and shifts in presuppositions – i.e., sharing indexical conventions. A basic issue is to show how these tasks are accomplished, and it is for this reason that IS puts so much stress on contextualization processes. Such metapragmatic activity is important for participation in everyday interaction. Without metapragmatic strategies, conversationalists do not learn and do not profit from their own misunderstandings. And this clearly has to do with verbal ability at the level of communicative practice, because it is on such practices that our ability to assess and evaluate the significance of what we perceive rests.

Let me present one more example to illustrate the multiplicity of inputs to the interpretive process. A young elementary school student, when asked to read, replied, "Ah ca-an't read." The teaching assistant thought he meant to say that he was not able to read. Examples like this have often been cited in the literature on classroom learning in support of assertions that African-American students have difficulty with literacy learning. But when we discussed this example with a group of African-American graduates, they pointed out that the expression carried contoured intonation, and given the expression's positioning after the teaching aid's question they

would interpret the student as saying, essentially, "I don't want to do it right now. I want company in reading." On the basis of experiences like these I became alerted to the fact that for those familiar with African-American conventions, the differences between 'contoured' and 'noncontoured' intonation may carry information.

Such uses of prosody are not only found in African-American speech. Consider the following example I recently heard in Cambridge from someone talking about his college, King's. "Fellows of King's are well known, to fellows of King's." The second phrase is set off from the first, and therefore foregrounded, by lowering of pitch and volume. This suggests that *well known* is restricted, so as to highlight the interpretation, and that the compliment phrase applies only to other fellows of King's, not to the public at large. Understanding, as structuralists have taught us always relies on selective perceptions based on our knowledge of oppositions, and this is true for indexicals as well as for symbolic relationships. All interpretive assessments are relational. They are made with reference to something else, not necessarily directly represented in talk. Nevertheless, as the examples show, assessment involves reasoning that is intrinsically dialogic, in the sense that positioning within an exchange is essential to communication.

Conclusion

Interactional sociolinguistics does not claim to present an integrated grand theory of language, culture, linguistic ideology, interaction, and communication. In view of the many radical transformations that mark much of the known world, such a theory would be premature. Rather, it draws upon an eclectic array of recent theories to find ways of uncovering the phenomenological grounding of communicative problems in today's social life to sharpen our understanding of the multiplicity of forces that underlie interpretation and thereby draw on what we have learned in recent years to prepare the ground for more productive theorizing.

Intercultural Pragmatics and Communication

Intercultural Pragmatics

In her book *The Opposite of Fate* the American writer of Chinese descent, Amy Tan (2003: 54), writes of a time when tragedy hit her life and when, as a result, she decided to quit the doctoral program in linguistics that she was pursuing at the time: "The doctorate, I decided, would be a worthless appendage. Besides (...), how was I bettering the world by teaching others to examine the intricacies of dead languages and the like?" Amy Tan's words echo these of the linguist Dell Hymes (1996: xii), who speaks of the fascination of modern linguistics with "aspects of language as an abstract formal device" and who sees as a more worthwhile and more timely goal "to think about language as part of life" (Hymes, 1996: x) and to develop a "linguistics that someone needs (...) – a linguistics that every student of human life should know, that one would like everyone to know (...), that should be part of general education" (Hymes, 1996: 220).

Intercultural pragmatics is a part of contemporary linguistics which is most concerned with "language as a part of life," indeed, with language as it affects millions of lives in the contemporary world, and which arguably every student of human life should know. It is a discipline that has developed in response to what Istvan Kecskes (2004), the editor of the new journal *Intercultural Pragmatics*, calls "the challenges of a new era."

These challenges of a new era involve, above all, interaction among people from different cultures. Pragmatics as a part of linguistics has always been concerned with interpersonal interaction – but (as will be discussed below) in the past it was often locked in a monolingual and monocultural framework, derived, essentially, from the English language and Anglo culture. In the contemporary world, however, a monolingual and monocultural perspective on language use is no longer tenable, and in fact has become glaringly irrelevant and obsolete.

In a recent book entitled *Becoming Intercultural*, the Korean-American scholar Young Yun Kim (2001: 1) writes: "Millions of people change homes each year, crossing cultural boundaries. Immigrants and refugees resettle in search of new lives (...) In this increasingly integrated world, cross-cultural adaptation is a central and defining theme." Cross-cultural adaptation is particularly relevant to immigrants and refugees, but the need for cross-cultural understanding extends further. In modern multiethnic societies, newcomers need to learn to communicate with those already there; and those already there need, for their part, to learn to communicate with the newcomers. In a world that has become a global village, even those living in their traditional homelands need to develop some cross-cultural understanding in order to be able to cope with the large world confronting them in a variety of ways.

Language has been defined, traditionally, as a tool for communication, and linguistics as the study of language. In practice, however, the dominant linguistic paradigm of the second half of the 20th century

had very little to do with human communication, and even less with problems of cross-cultural communication. In the last three decades, however, linguistics has 'greened' and the formalistic approaches of generative grammar have been supplemented, if not supplanted, by approaches more concerned with meaning, culture and people, than with formalisms.

The "pragmatic turn" (Mey, 2004) in linguistics is part of this 'greening.' But the paradigms of pragmatic research that at first came to the fore were derived largely from philosophical speculation based on English (especially in the works of Austin, Searle, and Grice) and did not reflect the mass phenomenon of interaction among people from different cultural backgrounds. As Kecskes writes in his editorial in the first issue of *Intercultural Pragmatics*, "We live in an age of globalization that is characterized by rapid changes in every field of life. This is resulting in a revision of theories and ideas in several branches of the humanities and sciences, including pragmatics. The existing paradigms cannot always accommodate new research. This is especially true for pragmatics, which is considered a perspective in language and communication rather than the study of a particular aspect of language" (Kecskes, 2004: 1).

Intercultural pragmatics studies, above all, problems arising in communication between people with different cultural backgrounds and different cultural expectations. A good example of such problems is provided by Amy Tan's account of the difficulties that her Chinese-American mother continually faced in her interactions with other Americans. As Amy Tan reports, "... some of my friends tell me they understand 50 percent of what my mother says. Some say they understand 80 to 90 percent. Some say they understand none of it, as if she were speaking pure Chinese. But to me, my mother's English is perfectly clear, perfectly natural. It's my mother tongue. Her language, as I hear it, is vivid, direct, full of observation and imagery. That was the language that helped shape the way I saw things, expressed things, made sense of the world." Amy Tan's mother's English was fluent, but its grammar was non-standard, and her way of speaking made it appear "fractured", "broken", "limited" – and her "limited" communicative competence made her also appear to be limited as a person. "I know this for a fact, because when I was growing up, my mother's 'limited' English limited my perception of her. I was ashamed of her English. I believed that her English reflected the quality of what she had to say. That is, because she expressed them imperfectly her thoughts were imperfect. And I had plenty of empirical evidence to support me: the fact that people in department stores, at banks, and at restaurants did not take her seriously, did not give her

good service, pretended not to understand her, or even acted as if they did not hear her."

Aware of the limitations of her communicative competence in English, Amy Tan's mother often got her daughter to speak to people on the phone pretending that she was her mother. For example, when Amy was fifteen, she had to call her mother's stockbroker in New York presenting herself as "Mrs. Tan."
